Bion: It is possible that the time could be measured by the oscillation from one to the other. One is certainly familiar with people who say, "I can always wake up at the time of day I want by thinking about it overnight; if I want to wake up at five in the morning, I wake up at five in the morning". I do not find that inherently improbable. What it is due to I do not know. It may be dependent on something physiological like the heartbeat, or something like an oscillation from omnipotence to helplessness. I think it might be worth investigating if you have a patient who shows that sort of oscillation. As it is, at present one depends on a thing like a piece of machinery which says a quarter past eleven, and we all have to be awe-stricken by it; we have to be impressed by the fact that that piece of machinery has got round to those particular positions of the hands. So I suppose we had better bow to our little watches.

4

I want to discuss something which seems to be far removed from the topics with which we are concerned. In recent years there has been a mechanical development in astronomy analogous to the discovery of the telescope. Hitherto astronomy has been limited by what can be seen by the visual apparatus of the human being when extended by powerful instruments like the two-hundred-inch reflector at Palomar. It has now been further extended by the discovery of radio astronomy. Radio astronomers have discovered what they call 'black holes' in the spatial counterpart of the astronomical field; they believe that the 'black hole' is the space where a star has become so concentrated that it has fallen in on itself – it has collapsed. Where there used to be a star there is now a 'black hole' which, they suspect, is the source of immense power.

I am familiar with a psychoanalytic theory of the human mind which sounds like the astronomical theory of the 'black hole' – as far as I can understand astronomical formulation. Why should a psychoanalyst invent a theory to explain a mental phenomenon and, independently, the astronomers elaborate a similar theory about what they think is a black hole in astronomical space? Which is causing which? Is this some peculiarity of the human mind which projects it up into space, or is this something real in space from which derives this idea of space in the mind itself? Perhaps someone may have time and the inclination to investigate this 'black hole'. Of course, the investigation might result in a negative discovery, a discovery which made it unnecessary to look further; or perhaps psychoanalysts have already suspected a peculiarity about the human mind, and if their suspicion is correct it will lead to still further psychoanalytic investigation and theories. I have used this idea of modern cosmology as a

model for psychoanalysis, but I would also use psychoanalysis as the starting point of an investigation of the human mind.

Let us look at something which is not millions of light years away, but very near indeed – oneself. Freud, when writing to Lou Andreas-Salomé, said that when he was investigating a very dark subject he sometimes found it illuminating to investigate it by artificially blinding himself. In the third book of *Paradise Lost* Milton says, "Hail, holy Light, offspring of heaven first-born! Or of the Eternal coeternal beam May I express thee unblamed? Since God is light, And never but in unapproached light Dwelt from eternity – dwelt then in thee, Bright effluence of bright essence increate! . . . Won from the void and formless infinite!" There seems to be no doubt, and Milton certainly had no doubt, that he was blind – "so thick a drop serene hath quenched these orbs which roll in vain"; although they can feel the warmth he can see nothing. A capable eye specialist would nowadays have ideas about the nature of Milton's blindness. We cannot really say whether Milton blinded himself artificially, or whether he realized, unconsciously, that he could not investigate these 'things invisible to man' while he was blinded by the brilliant light of facts. One cannot psychoanalyse Milton, but it is puzzling that he could apparently turn the experience of being blind to good account, exactly as Freud could not investigate these dark and obscure places unless he artificially blinded himself.

When we are seeing our patients tomorrow would it be a good thing to know as much as possible about psychoanalysis, to have as brilliant an illumination as possible to bring to bear on the facts which we shall come across in tomorrow's session? Or would it be better to blind ourselves artificially so that the dark should be so pervasive that any very faint object will show up – like the expression about looking for a black cat in a dark cellar without any light. We can consider, as our patient talks to us, which we had better do: know all that there is to be known by one person about psychoanalysis? Or be as forgetful as we can of the various facts in order that our intuition, however feeble, can have a chance of seeing something, however faint and however obscure, in what the patient is saying to us? We need a kind of mental binocular vision – one eye blind, the other eye with good enough sight. The English admiral, Nelson, once decided that it was wise to 'turn a blind eye' to a signal which had been made, to disobey orders, so that he could say he had not seen the signal. He put the

telescope to his blind eye. Are there not times when it would be just as well if we did not pay too much attention to what we had been told to do? Where no interpretation that we know and that we have been taught (rightly taught by our forebears) seems to illuminate the situation, would it be as well not to see what we are told to do, but to use our own initiative? A most dangerous thing to do! It is arrogant, and in some ways you have to be a bit of a fool to ignore everything that you have been told and imagine that you would know better. But even in our own childhood our parents were sometimes wrong; they knew much more than we did about how to bring up children, but sometimes, when we were being really naughty, we may also have been quite right – no credit to us. Can we mobilize that today when we are grown men and women and are still feeling that we have a lot to learn? We are both the children, as it were, and the grown-ups. Shall we forget what as children we learnt was right, or shall we forget what as grown-ups we have also learnt is right? How can I put to you that I think you ought to use your intuition, however feeble and however misleading and however dangerous the possible wrong path may be?

To look now through the other eye – to return to astronomy. While most people were saying, "This is a terrible radio; I can't possibly hear the programme; the music is drowned by interference", some difficult, perverse, stupid, ignorant individual decided not to listen to the beautiful music and decided instead to listen to the interference. Can you imagine anything more perverse, more stupid than that – not to listen to Bach or Beethoven, but to listen to the interference? Nevertheless, not so many years later somebody built enormous radio telescopes to listen to this interference, to listen to the background noises. So much for our crackpot, stupid, psychotic, perverse and tiresome people! Why are they the people who are picked out to make these discoveries? Why did Galileo go against all the authorities, including important religious authorities, to say that the universe was different from what the representatives of God on earth had said was the fact? We cannot very well say, "Don't let's bother about sane people; the people we really want to encourage are all our lunatics". But we certainly cannot afford to say, "Here are the sane; there are the lunatics". It is a fact that the rebellious psychotic of one moment is almost instantaneously transformed into the sane, charisma-invested Establishment of the next moment.

In this narrow sphere which I might call 'myself', I have to try to have some opinion as to whether I am talking nonsense, or whether I am saying something which it is worth somebody's time to listen to. In the world of thinking when one is doing the kind of thinking which is a prelude to action, and not a substitute for it, one has to decide, even though one has not much to go on, whether it is worth while bothering people by mentioning an idea that one has. It may not be nonsense. That is the dilemma which confronts every one of us in this tiny universe which is the universe of ourselves: a universe which seems to be rather bigger than what, if we could fall back on anatomy and physiology, one could say was 'oneself'. I could have a good idea who I am if I was allowed to consider that my boundary is the same thing as the boundary of my skin. But I wonder whether my mind is really inside my skin with the rest of the works. If we have this psychoanalytic prejudice which is based on the theory that there is something which it is worth calling the human mind, and that it is worth investigating, it may be as important as all these radio interferences which are worth while attending to instead of the programme which our betters have decided is what we ought to listen to.

Our patients tomorrow *mean* to tell us some things and we ought to listen to what they have to say. There is no question of ignoring that. But one could say to the patient, "As well as what you are telling me, I would like to draw attention to what you *don't mean* to say – some stuff which you may think is rubbish. I would like you to have some respect for your mind as you know it and for parts of your mind which you have so far thought were rubbish", and which, according to Melanie Klein, infants split off at an early age (or think they do) and get rid of (or think they do) in the way that they learn to get rid of urine because it is not milk, and faeces because it is not good to eat. One neither drinks nor eats one's mind, but the habit of splitting off can continue; there can still be a wish to be able to say, "I don't want to have anything to do with all the bad stuff that I have ever got rid of". The analyst is saying, "Do have a look at this bad stuff; do have a look at the stuff which you have thought is bad at some time in your life and have tried to get rid of". In psychoanalytic practice 'looking at' is inseparable from experiencing 'turbulence'. This mixed, chaotic confusion may perhaps be the contents of the mental 'black hole'. That is why individuals often prefer 'hearing about' than 'experiencing' psychoanalysis. So before getting rid of the 'black

hole', have one more look at it before you decide that everything that your fathers and mothers told you was rubbish; before getting rid of all our conscious, rational knowledge, let us have a look at that too. In short, let us have a look at the interferences.

There is a complication; you will not be surprised that we shall now look at it. The baby in us hates the grown-up; the hate is mutual. Tomorrow one of our patients may show every sign that he does not want to grow up – he thinks it is a bad idea. He would rather remain a baby all his life. I myself am glad that I am not an official of a psychoanalytic society; let someone else be grown-up and do that job. Equally, the analysand does not want to be reduced, as he fears he will be, to the state of mind of child or infant. But it is not something which is over and done with once and for all. We remain human animals: sometimes young human animals; sometimes one can say we are grown-up human animals. Can they be made to work together? Can they co-operate enough to produce, to use metaphor, binocular vision, bi-mental perception? Are we on the right track as analysts? We assume that there is a mind, that it is worth spending time and money on it, that it is worth spending time on that particular specimen of the mind that we shall come across tomorrow. That is what *we* think. But we are a very, very small minority.

Q: You have stressed the importance of respect for mystery, and of the psychoanalyst's intuition. How can one reconcile this with the preference given to medical background in selection of candidates, since this training generally gives an organic-based, rather than an intuitive, attitude. Would it not be better to give preference to those with a humanities background?

Bion: This problem always exercised the British Society and was a matter for continual debate. In general it was agreed that one third membership should be lay members, the main requisite being that all the members should show some signs of a sincere devotion to the work. If a person was medically qualified it showed that they had undergone a discipline. The lay member, likewise, was expected to know what it was to be part of a mentally disciplined organization, such as having studied enough to get a degree in, say, philosophy. There is a lot to be said for the medical discipline as a preparation for the practice of psychoanalysis; doctors are familiar with anxious and frightened people. But on the other hand, they may be handicapped

by a materialist prejudice. To exaggerate: you can palpate the abdomen and you may feel a lump in it; if you cannot palpate the mind, then it is absurd to say there is anything wrong with the mind.

We must hope that our selection committees may exclude the worst and not exclude the best. This problem of selection has to be a matter of endless review; we have never answered the question once and for all, nor can we find an answer which absolves us from the need of thinking out every case on its merits.

Q: I would like you to tell us something about the black hole of silence in an analytic session; also something about the curious light of hallucination by which one perceives the invisible.

Bion: When we listen to a piece of music, included in it are the pauses, which in English one calls 'rests', but they are part of the music. I was once asked about groups, "Do you ever do anything except talk?" I said, "Yes, we are silent". I think that the questioner, who was a doctor of philosophy, thought I was being funny. But I was being serious. A group of people are not always talking; they are sometimes silent and that silence is a part of what they are doing. In English we even have an expression, 'a pregnant silence'. It expresses it very well. There are some silences which are nothing; they are mathematically zero. But there are times when a zero is put between the figures 1 and 1 and it turns it into one hundred and one. Similarly, there are some silences which turn the preceding sounds and the succeeding sounds into a valuable communication. A good poet uses ordinary words and ordinary silences, but the use to which he puts them turns both the words and the silences into something which is extra-ordinary. In analysis you may be able to distinguish the silences which you have a chance of observing. In 'practice' you can; in 'theory' you cannot.

It is difficult to distinguish between zero, meaning nothing, and something which is important, between a silence which is empty thought, and a silence which is pregnant. If I were talking about physical sexual intercourse and the consequences – pregnancy and so on – these words would be all right. But I am not meaning to talk about anatomy or physiology: I am talking about a mental experience. The problem is to interpret the silence, or to interpret what seems to be a silence. John Rickman described to me a patient who covered himself completely with the blanket, with the exception of one

eye – that was all that Rickman had to interpret. It is no good trying to look that up in analytic books; it is no good asking anybody else what the interpretation is. You have to go there, you have to have a patient who behaves like that, and you have to be able to stand it long enough for something to emerge. Freud describes how a mathematician has to look at a mass of meaningless, disjointed, disconnected facts until he thinks he sees a pattern and can write that pattern down in a mathematical formula.

What kind of analysis is required to interpret the behaviour of a patient who uses silence extensively, the patient who comes to you, says nothing at all, and walks out apparently satisfied at the end of the session? If we are going to restrict ourselves to verbal intercourse between the analyst and analysand, I do not think we are going to get far with that kind of patient. The analyst's 'restricted' statement and the patient's 'silence' leave too big a gap and no link between the two sides; 101 remains 11. It is not one hundred and one; it is not eleven. Someone will have to invent the language of silence – the unexplicit silence.

I had a patient who, when I spoke to him, would watch my words float over the room until they made a pattern on the curtain – so he thought. When his behaviour became comprehensible to me, although he never said a word, I could try to put it into words and it seemed to have some result. That is the kind of problem we are up against. We say, "This patient is being hostile", but we may be using the wrong psychoanalysis to interpret that silence. When you see your patient tomorrow, not only do you have to pay attention to what is going on, but you may have to invent the tools with which to do that analysis while you are doing the analysis: like a Galileo who has to invent a telescope, make a telescope, and grind his own lenses in order to study the matter he wants to investigate.

Q: What would 'interferences' be in psychoanalytic terms?

Bion: When you are talking to your patient you can sometimes see and feel that he is not attending to you. At the same time you can feel that he is attending to *something;* the conversation between the patient and analyst is being interfered with. That is what I mean by interference. Are you going to pay attention to what he tells you, or what your books have told you, or are you going to pay attention to the interference? This is the difficulty about practical psychoanalysis; this

is the difficulty about tomorrow's sessions. It is no good saying, "You are not free-associating", or, "This patient doesn't talk to me, I can't do anything about him". You can be silent; and you can listen. You can stop talking so that you can have a chance to hear what is going on. What you have to listen to then is psychoanalytic 'interference', just as somebody had to listen to radio interference. There is little chance of progress in these areas which we ordinarily call psychosis, or border-line psychosis, until we listen to what is happening – in this sense of being able to be silent when it is necessary.

You have illustrated the need for a language in your question, only you are asking me to invent the tool with which to ask, as well as answer, your question when you ask me, "What . . .?" There are no psychoanalytic terms known to me, any more than they are known to you. We both have to borrow from other disciplines.

Q: I would like to hear more of your comments on curiosity. Are there different kinds of curiosity?

Bion: What *I* think about curiosity, or different kinds of curiosity, is not important. You must have respect for yourself and your capacity for listening to, or looking at what is going on in your consulting room. That is the place where you will find the answer – not from me, not from any book, not from any colleague. When you sit there being curious you may have a feeling that the patient is now being silent in a different way. Suppose the patient begins to talk and ask you questions. You may feel, "This curiosity is a request for help". The same question may be repeated over and over again, like the patient who said to me, "I don't know what I mean" [see p. 18]. While you listen to the patient being curious you could say, "This patient is asking these questions to make me angry". Later, "This patient is asking me these questions because he wants to evoke some information about me". In that way you could note the different kinds of curiosity. That would be on the right track – asking me is not; going off to the library is not. The best place to find the answer to that question is in your consulting room listening to the patient being curious. I shall look forward to the book of your lectures on this subject. That is more important than the book you are reading now.

Q: Do you think the feeling of beauty can be taken in analytic work as an indication of truth, as Einstein considered it an indication of scientific truth?

Bion: I think you must be referring to something like Keats's statement "Truth is beauty, beauty truth". Scientists tend to feel that they are concerned only with the truth, only with the facts. Recently there has been considerable criticism of Linus Pauling for saying that vitamin C was a cure for the common cold. Doctors said, "What nonsense this is!" It is a dangerous thing to tell a Nobel prize winner that he is talking nonsense. He may be – nonsense is nobody's private property. But a Nobel prize winner will be likely to have a very good answer to that challenge, and Linus Pauling was able to show medically qualified men, often highly medically qualified, that he was not being unscientific.

Suppose one changes what I call the 'vertex'. We move off the scientific vertex to the aesthetic vertex. The definition of truth may be all right in logic, in scientific method, but that definition may not be applicable in the universe of discourse to which we have changed when we have changed the vertex to aesthetic, to the standards of beauty or truth in the aesthetic sphere. If I were to draw a picture of a human being I think you might be justified in saying "What on earth is that? That isn't like any animal I have seen on earth." But suppose Picasso drew it. One could say, "Well, if I want a portrait of my wife, or my husband, I don't think I'm going to get Picasso to do the job. I don't think that is at all a pretty picture." But the extraordinary thing is that when you are looking at a genuine Picasso you get a feeling, "You know, I think I see what this chap means – it's not quite what I could interpret as 'that's my wife', but I can say 'that is about something; that isn't about nothing'". That painting by Picasso is not adequately mathematized by the zero 0. You may feel that you do not really know enough to be able to understand what Picasso shows you.

You may give your analysand a correct interpretation, an interpretation which you are sure expresses the truth, and yet the patient may say, "I don't understand this psychoanalytic nonsense!" You can only say, "Well, you feel that it is nonsense; but perhaps you may feel it is 'non-sense' later" – and leave it at that. Many of our interpretations which are obvious to us as psychoanalysts may seem extremely obscure to the patient. He may sincerely say, "I think it's nonsense". But sometimes analysis is accompanied by the growth of mutual respect. The parents may have had something to teach the child. Today the grown-up child knows more than he used to know, but he

is also the child who could teach him something. After all, the child must have known enough to have grown up and still to be surviving. Sometimes analysis is accompanied by growth of the analysand's respect for himself.

One can identify oneself with the analyst, or one can identify oneself with the analysand. One can feel, "I can understand that he doesn't understand my interpretations, but as a matter of fact I have no reason to alter my interpretation; I think it is true. I can quite see that he thinks it's nonsense. Time will tell." Time is telling.

5

We have all experienced the patient who says, "I can't think of anything to talk about". That is an extraordinary state of affairs, for no one has said that any subject is debarred from discussion and there is a whole universe to talk about if the patient feels so inclined. The psychoanalyst is not in the same position although he is present for the same fifty minutes and in the same room; his working occupation limits his range of discussion. The minimum range suggested by Freud was discussion of the Oedipus situation, the interpretation of dreams, and sex. The work would indeed be limited if it in fact applied only to that threefold area, but each of these main topics splits up into a number of subdivisions, and these in turn become further subdivided, and so on, until before long there are an enormous number of possible interpretations. It depends upon whether you take the restricted view of the common root of the interpretations, or the various varieties. The mental domain is wider still when it is considered that the main categories change according to the vertex: for example, religious, aesthetic and scientific.

The conversation which takes place in the consulting room should resemble real life; painting should produce pictures which in some way remind you of the world we live in; similarly with sculpture. But people change, and a Greek who admired the sculpture of Hermes of Praxiteles would not understand a sculpture by Rodin who attempts to portray the character rather than the physical appearance of a person.

Already these topics have expanded in an alarming manner into a vast area of discussion. It diminishes equally rapidly when the patient says, "I can't think of anything to talk about". What are we to say, what are we to think about this situation? Does the patient

regard the range of talking as too limited? Is he somebody who says, "I can't talk. It doesn't give me any scope. I could play my violin to you – then I would have something to say." We may think, "This patient is denying something", but that can be an over-simplified and restricted interpretation. It is not enough to say he is denying reality – we need to know what he is affirming. We already have seen that if he is affirming reality we need to know what he is excluding. (I am doubtful about terms like 'excluding' or 'denying' in the consulting room, though they are useful in discussion about analysis.)

After the patient has said that he has nothing to talk about we wait – in 'expectant' silence. What are the possibilities? As you see the patient lying there saying nothing, it may occur to you that his silence is intended to find out something. Is he saying nothing so that the analyst will have to ask a question? The analysand will then find out what the analyst is thinking, or whether he is in a bad temper or not, or if he cares whether the analysand has come or not. You may feel, "This silence is evocative. I think this patient is waiting to see who lets which cat out of the bag first." We know nothing about whether it is right or wrong, but if you wait, your 'hunch' may become a certainty. If someone asked you why you thought the patient was being evocative you could only say, "If you had been in the consulting room with me you wouldn't have any doubt about it any more than I have". In a scientific meeting it is difficult indeed to explain that. That is why people often get irritated; it is just the sort of experience calculated to make everybody feel bad-tempered.

Freud says that it is important to be able to pay attention to the patient; to watch, listen and hear what is going on until a pattern emerges. Poincaré says that a lot of meaningless and unconnected, discrete facts make him, when he has contemplated them for long enough, think of a mathematical formula; then he realizes that the mathematical formula explains many facts which have not been explained before, and then, if you are lucky, it also explains a whole lot of facts which you had not considered. In analysis one sometimes hits on an interpretation which makes clear a lot which one has not understood so far; not only that – it also explains a lot of things which happen in the next three or four sessions and which have not happened before. When this occurs the analysis seems to progress rapidly. We are so used to analysis taking a long time; but some things happen with incredible speed. For example, you give the patient an

interpretation for what seems to be the hundredth time – without the slightest effect. He says much the same thing as usual, "I haven't really got anything to talk about". You try again, and just as you are getting exasperated and are thinking, "Oh, dear! Number hundred and one, hundred and two, hundred and three" – counting interpretations is quite as effective as counting sheep for sending you to sleep – the patient starts talking to you and you think, "My goodness, he's woken up! He sounds alive. His intonation is quite different. Instead of talking in that terribly dreary, boring manner which makes it almost impossible for me to stand the experience, he is talking in a lively, interesting manner – this same patient who had nothing to say." You are liable to be so surprised, so gratified that you either forget that the situation is probably just as dangerous as it was before, or you fail to recognize that the patient has altered and fall into the pattern of looking forward to a never-changing, never-ending analysis. You need to be able to stand the fact that the situation which has in fact changed a great deal – the patient has changed a great deal – has in some respects not changed at all. If, for example, you are satisfied that that patient is a dangerously irresponsible man, he is almost certainly still a dangerously irresponsible man, but the variety has changed. He has four, or fifty ways of being irresponsible and dangerous – instead of only one. To put it in more theoretical language, the basic things do not alter; art, science, religion do not alter. These are fundamental characteristics of the human animal. The superficial variables, to use a mathematical term, do alter.

I can describe this situation in a simple, pictorial way, thus: – $\psi(\xi)$. ψ stands for psyche and is constant; ξ is a variable; it goes on changing, changing, changing the whole time. The totality, say a man or a woman, remains recognizably the same, constant, otherwise you would not know that this patient had come to see you yesterday, the day before that and so on; nor would the patient. But there are also elements which are variable in spite of all the constancy. In analysis we have a chance of seeing the perpetual mystery of this peculiar process, described by Confucius (translated by Ezra Pound) who talks about adult wisdom consisting in seeing how things grow and change, grinding in the "mortar of the mind". The interesting and pleasurable component of psychoanalysis is that one has a chance of watching the way that people grow. In family life, similarly, someone

with a chance of paternity or maternity can watch how children grow – a fascinating and rewarding experience.

The child does not have that experience, because it cannot understand that it has much to do with growth. It is one of the reasons why a patient can be dominated by the feelings of fear of his being extremely destructive, of his feeling that even if he loves something he loves it in the way that he loves his food – he chews it up and turns it into faeces and urine. That is fairly easily and quickly understood by the child, but it is a long time before a child is able to learn that as a result of what he eats he does in fact grow. By the time he is able to stand against the wall and see that last time he was four feet three, but that now he is four feet three and a half inches tall, the conviction that he destroys what he eats has become firmly established. Analysis would be like being able to introduce him to the idea that he has grown, and introducing that idea to his feelings of depression, hopelessness, boredom and anger. He has often heard "You *are* a naughty boy; why do you break everything up?" He cannot say, "I have only been breaking up my breakfast – or my lunch or my tea – because I hope to be bigger" – as a child he cannot argue like that. These two people – the destructive, hopeless, despairing person, and the creative, constructive one who grows – do not meet unless we can manage to introduce them to each other in analysis. We are not attempting to show the patient how bad he is or to make him feel he will never be any good. We are trying to show him why he is so depressed, and that although he may know nothing about it he actually makes something out of his food which is not only faeces and urine. The girl has a chance of feeling that she may be able to make babies and that can bring a certain degree of relief. The boy, on the other hand, hears that his little sister can make babies, but that he cannot. It is easy for him to understand that; it is much more difficult for him to understand what good he is. Even in genital intercourse the man can feel that his contribution is slight indeed; even if he can have intercourse, what he does is very little compared with what the breast does – or his mother, or his sister. The analytic experience is not simply to find out about the boy or girl, the man or woman, in the sense of finding out what their faults and mistakes are. It also means giving them a chance to see that it may be perfectly true that they smash things up, but it is not the whole of the truth.

Q: Do you not think that the difference between theory and practice in psychoanalysis is due to the exercise of the profession by human beings, and that the difficulties over theory and practice are partly due to the analyst's fears of his own unconscious – thus he shies away from theory and memory? When you suggest forgetting theories and preconceived notions, are you not asking us to rely on the working of our unconscious, our mental apparatus, where not only Thanatos but Eros lives?

Bion: If we were not humans we would be no good as psychoanalysts. If we are human beings then it would be foolish to think that we escape the failings that we shall find in our analysands. In analysis we hope that we may be able to see the immediate difficulty which the analysand is having; but there is no one to whom the analyst can turn to help him with the mistakes that *he is* making. One can only hope that our own mistakes will be at a minimum. At some time we are sure to have a patient who stimulates our weak points. In other words, we are the analysts who the patient should not have. But we do not always have the parents who would be the best kind of parents for us; nor do we always have the kind of children who would be the best possible thing for us. When it comes to a question of choice, we do have a chance to choose the company we keep. We can choose what sort of professional society to belong to. We can choose, to some extent, the kind of parents with whom we would like to mix – even if they are somebody else's parents. That is why, in childhood at any rate, the disadvantages of having a particular mother and father are modified by the fact that we can work out some of our problems with a grandparent, or an aunt or uncle. Let us hope that something of the same kind applies to grandchildren and nephews and nieces. If we are not having quite the experience that we feel is good for us with our children, at least we might be able to have a better time with our grandchildren and nephews and nieces. The alternative is to make the best use of the kind of parents or children we have. Some people can do that. It is not that they are better off, they are better off because they can make good use of their misfortunes. Sometimes the individual has the misfortune, so to speak, to be very fortunate. A girl can be so beautiful that everybody automatically admires her. To be as beautiful as that a girl requires a great deal of wisdom. So often she seems to be a fool. It is difficult to realize that you have

to have a lot of wisdom to make the best of your misfortunes; it is much more difficult to see that you may have to be very wise to survive being well-endowed. Such a person may get so used to having everything without any difficulty that when they have to deal with the real world, which after all stays very much the same, they go to pieces – they have had so little experience of making the best of a bad job. They only have the experience of making the best of a good job, or even of making the worst of it.

Q: Could you say more about your reference, during supervision, to 'unborn babies'.

Bion: The poet Bridges says in *The Testament of Beauty* that wisdom consists in the "masterly administration of the unforeseen". The unforeseen is, in my analytic experience, one example of 'unborn baby'. In analysis the 'unborn babies' are the ideas which have not yet cropped up, but may do so at any moment. They may be good ideas, or they may be bad ideas, in much the same way as a baby might turn out to be a nice child or a nasty one. The analysand should become capable of coping with the 'unborn babies', the ones which have never been born, but which might be born at any time. If one has respect for persons, then every patient is potentially an 'unborn baby'; any idea is an unborn idea if nobody has formulated it so far.

This discussion is full of examples of what I mean by 'unborn babies'. I leave it to the reader to 'administer' those which he had not foreseen.

Q: Bearing in mind your references to the respect due to the human mind and personality, what do you think are the factors or motives that should lead one to fail a candidate?

Bion: In all my years of experience of selection in the British Psychoanalytical Society I cannot say I have found the answer to that question. We do not qualify everybody and sometimes I think that amongst the ones we have not qualified are, unfortunately, people who are a great deal better than those we have qualified. We have to make these decisions, making use of such intelligence as we have, but we may not have enough wisdom or intelligence to make the right decision. It is a human failing; the wrong people are chosen to be members of a football team, or to be surgeons or physicians, or parsons, or prime ministers. The supply of prime ministers is small,

but it is extraordinary how, even so, we can choose the worst ones. A friend of mine used to talk about what he called 'self-selected unsuitables': someone is put forward for a job because he has chosen himself for that job. There is a large supply of them. In the army there were people with self-inflicted decorations – inflicted on themselves as a way of getting out of certain very unpleasant difficulties.

I would not feel disposed to qualify somebody who disliked people unless the people were likeable. Most of the time we have to deal with people who have failed, or who are not very good at their job. Those are the people that we have to make able to be good at their job. Someone may have made a mess of everything he has ever had – education, fortune, married life, all of it – and yet will expect an analyst to make a success of him; and the analyst is expected to make a success of making a success of such a person. He will not do that if he dislikes people.

Q: I would like you to say something about the use of counter-transference in analysis.

Bion: Counter-transference is a technical term, but as often happens the technical term gets worn away and turns into a kind of worn-out coin which has lost its value. We should keep these things in good working condition. The theory about a counter-transference is that it is the transference relationship which the analyst has to the patient without knowing he has it. You will hear analysts say, "I don't like that patient, but I can make use of my counter-transference". He cannot use his counter-transference. He may be able to make use of the fact that he dislikes the patient, but that is not counter-transference. There is only one thing to do with counter-transference and that is to have it analysed. One cannot make use of one's counter-transference in the consulting room; it is a contradiction in terms. To use the term in that way means that one would have to invent a new term to do the work which used to be done by the word 'counter-transference'. It is one's *unconscious* feelings about the patient, and since it is unconscious there is nothing we can do about it. If the counter-transference *is* operating in the analytic session the analysand is unlucky – and so is the analyst. The time to have dealt with it was in the past, in the analyst's own analysis. We can only hope that it does not use us too much and that we have had enough analysis to keep the number of unconscious operations to a minimum.

6

Democritus of Abdera first put forward the theory that the brain had something to do with thought. Even today, some two thousand years later, we are still in a rudimentary stage of knowledge of the functions of the central nervous system. There are extensive accumulations of knowledge and experience of the anatomy and physiology of the brain. It is hard to say, however, what are the anatomical or physiological structures of the mind – assuming there is one – or what relation exists between the mind and the central nervous system. For example, has the sympathetic system, or the para-sympathetic system, anything to do with the mind or the personality? Is the mind (a theoretical concept) as important as the anatomical and physiological central nervous system?

As psychoanalysts we are concerned with trying to formulate why, and in what way, we think the 'mind' important. We assume that the vast amount of psychoanalytic literature is a product of the mind, a way of delineating the mind as a reality, as the reality that corresponds to the theory that there is such a thing as a mind or personality. One might argue that if there is a mind then it should be possible to find some event which could be regarded as the product of the mind, a result of the existence of a mind. Suppose that the psychotic person could produce some physical representation, would that representation betray the presence or the nature of that particular kind of mind? Would pictures drawn by a psychotic all betray a similarity so that if one looked at hundreds of pictures one would say, "Yes, I can put fifty, sixty, eighty of these drawings together and I think they would all of them show certain characteristics"? And if I could interpret what is the pattern of those characteristics, then I would discover that they were all the product of a certain kind of

mind. Criminologists are confident that finger prints provide a means for identification of a physical being. They can compare, apparently to their satisfaction, the number of points which have to correspond to identify the one print with another. We have no similar scheme by which we can compare one mind with another. This is so even in what appears to be such a gross difference as might exist between male and female.

The refinement which I visualize might show the mind could betray still more subtle, physical states, or even the germ of the physical state, before it emerged so grossly as to be discernible to sensuous investigation. Note that I am postulating the prediction not of psychoanalytic developments, but of psychoanalytic developments which might betray a physical future. They are not mutually exclusive. The statistical formulation known as the Poisson distribution is an example: the distribution which is characteristic of extremely rare events, events which are scattered over a great area of time, or a great number of human beings, but are characterized by certain mathematical patterns. That would be something much too subtle for interpretation by a single individual, but it might be possible if the knowledge was accumulated over a period, shall we say, of a thousand years. In this way the accumulated wisdom of the race could discern certain patterns which were characteristic of the individual. Clearly this depends on something more durable than the individual as known to psychoanalysts.

Thus, we might be able to say, "This pattern is a pattern which is characteristic not of some physical disease which has not yet betrayed itself, but is characteristic of a certain kind of mind which has not yet betrayed itself". It depends upon what we could call 'direction'. In one direction it could betray a state of mind as yet unborn. In tomorrow's session it is necessary to know what state of mind is unfolding itself in front of the analyst. Further questions to be resolved are: is it a past, future, or contemporary state which is casting its shadow on the present screen on which we hope to delineate it? Stating this in psychoanalytic terms: the screen is the transference; the interpretation is to determine what it is that is being 'transferred'. In pictorial terms: there is the shadow; where is the source of illumination? The reader must translate these statements into language which experience shows him is most serviceable to himself.

We are all concerned with seeing patients, but what we see may not be comprehensible to us as analysts, because our lives do not last long enough. However, as parts of a race or a nation our work might be significant. As individuals we do not know much about what part of the whole we are, any more than one of the microscopic parts of our anatomy knows what part it is of the human body. Our work as psychoanalysts depends on our having great respect for the individual, but it is difficult to say in what way that individual matters as one cell out of a totality. It suggests that we need to be very sensitive to the observable facts. We should now be inventing a method of communication which will be comprehensible to our successors. It is not a matter of much importance to any of us as individuals, although it might turn out to be important one day, just as the heliocentric theories of Aristarchus turned out to be of great importance many generations later when people were able to produce a telescope, or a microscope, or take photographs of the spectra and notice the Fraunhofer lines and interpret them. All that depends on what turns out to be a combined operation of people who could never have known each other. Consider a matter like the Fraunhofer line typical of sodium: it is now known that the Fraunhofer lines have widths – not exactly what had been expected – and consequently that particular form of spectrum has to be analysed in a new fashion. It has a resemblance to the old fashion, but it is a new fashion. The Fraunhofer line is an example of 'interference' which someone has noted and studied instead of white light. "Life, like a dome of many-coloured glass, stains the white radiance of Eternity" [Shelley, *Adonais*]. We human beings, for all our self-importance, are a 'stain' on 'eternity'. Present-day analysis may one day become comprehensible to our successors.

If we are sufficiently sensitive to what goes on in the consulting room we may some time be able to understand what we see. I say, 'what we see'; of course we do not 'see'; there is nothing, as far as we know, which is visible in the range of ordinary sight. Let us use a term like 'insight' and say, it is still not within the range of ordinary insight – although it might be within that range if we can go on observing it through time and through generations of people. If we pay sufficient attention to what is being communicated to us by the patient other than verbally, say, by the use of gestures, we might increase our understanding during the short space of one working

life. If we could remain sensitive to the importance of the individual without being blinded by our own importance as the analyst, we might increase our contribution to human life – as did the inventor of the wheel, that unknown genius.

For example, a patient comes into the consulting room and does not say a word; perhaps he keeps on coming for six days, or six weeks, or six months without saying anything. If one can stand it, then after six months one might begin to think, "I have an idea about the pattern of this silence. I wouldn't like to say at any given moment why his silence today is not the same as his silence on Friday, and it won't be the same tomorrow. But I think that if I can go on listening to him being silent" – in the way that Freud talks about the importance of going on being present in the consulting room with the patient for long enough – "I begin to be aware of a pattern". Although we cannot say whether we have heard anything, we could say, "It has an effect upon me – not on my counter-transference – and I think I have had a respect for the silence of the session". If we cannot respect the silence – "I can't be bothered with this person; I can't come here day after day and have him lying on the couch, saying nothing" – then there is no chance of making any further progress. It is difficult to explain to someone not present why we think that we could hear the difference between one silence and another. The patient, however, *is* present.

As a somewhat gross description of the difficulty, let us suppose I have watched a child patient for six weeks; someone says, "Why do you waste your time doing that? Anybody can see it's an autistic child." Full stop. Finish. The diagnosis is simple – "It's an autistic child". All I can say is, "Well, *I* am an autistic analyst". If I want to make it sound respectable I can say, "I am a specialist in treating autistic children", or, "I am a specialist in treating adolescents", or, "I am a specialist in treating latency children". That may make it respectable, but it explains nothing. If I were honest about it I would have to say, "I listen to people who are silent for six weeks" and run the risk of being likened to the lunatic in the old joke who said, "Come inside", to the 'sane' person 'outside'. One has to tolerate the pressure from outside and be prepared to tolerate what it feels like to be inside that 'silence' as the patient can. The temptation is to rush to premature, precocious comprehension and diagnosis such as 'autistic child', 'adolescent', 'adult'. We have to say, "Well, yes, he told me all about going

to see the latest football match. I wasn't listening. But I did hear what he was not telling me, and that silence made quite a different noise; the pattern of what he didn't say showed that. . . ." When we see our patient tomorrow we must listen to what he says and to what he does *not* say; one has to 'intuit'. "I was listening to the silence; I was listening to the interference; I was listening to what came between him and me; I can now draw you a picture in words (or in painting, or in any other technique of human activity), a representation of what I intuited during so many minutes, or weeks, or years."

We need to be wide open to what is going on in the session. (This is what I think Freud means by 'free-floating attention'.) The unobserved, incomprehensible, inaudible, ineffable part of the session is the material from which will come the future interpretation that you give in so many weeks', or months', or years' time. The immediate interpretation was settled some time ago – one does not know when. We must concern ourselves not with what the patient is 'like', but with what the patient is 'becoming' during the session, and we must be able to stand the pressure of watching that process.

Q: I should like to have your comments on the following clinical material. The patient was a twenty-year-old man, a teacher of electronics, physics and mathematics, unmarried, the youngest of three children. He complained bitterly of his father's jealousy of his relationship with the mother. He said it had ruined his childhood. He was especially fond of food; a well-prepared meal drove him almost into a state of ecstasy. He said his mother is a wonderful cook. On the other hand, he sometimes existed on the simplest rations, feeling no need for dainties or liquids. Sometimes he had his meals away from home, choosing the worst food or bad cooking, eating without appetite. He became fascinated by a young man whom he described as having a long face, a thin pointed beard, a thin moustache and long, silky hair. He followed this young man to his apartment where they had promiscuous intercourse. He said the young man's face was round and not long as he had first thought, and was similar to his father's face. He said my face was also round. I said he was thinking that my face was also longish. Later I said he was repeating a recent similar situation. He looked deeply depressed and remained silent and withdrawn. I said he was reliving a situation he had lived through before, but

of which he could not speak – the primary relationship of breast feeding. He then looked at the Picasso painting, *Maternité*, and said "This picture disturbs me". I said he was now establishing a relationship between the time he had lost in infancy when he could not talk, and the present when he is able to communicate. He said he talks a lot, but the content of his speech is null. He could not distinguish between what he had lived through in the past when he was unable to define his impressions, and the present.

On returning from a journey undertaken to participate in a meeting of the faculty of the school in which he taught, he told me this story. He was driving his car at medium speed when a drunken woman jumped from the sidewalk directly in front of his car, and he, unable to brake, hit her. Witnesses said she had deliberately thrown herself in front of his car. As a result he was extremely upset and avoided any reminder of his past.

At present he is going through a difficult period in which he tries to escape from reality, avoiding a deep and intense existence. He cannot listen to music – which he formerly greatly appreciated – and abhors food. He avoids looking at the breasts of any woman; he relates the bad food which he eats in restaurants to the breasts of any woman.

This is the present situation – the difficulty of establishing this relationship so distant in time and so near his reality. When an interpretation makes him feel this relation with the past he becomes confused.

Bion: This patient is terrified of a guilty conscience with which he cannot cope. He feels he is responsible for the murder of the woman; he feels that he is reduced to travel to prove to himself his mobility and freedom to escape from 'the woman' who, as he always expects, is able to catch him up wherever, whatever, and whenever, and get herself murdered by him. His escape by aid of the onlookers is felt to be adding insult to injury by evading being held responsible for the murder of the woman. I suspect that he feels similar guilt about any progress in the analysis which might be conducive to further life; the more profitable, the more guilty and the more likely to be 'fascinated' – being fascinated meaning what we would call repetition compulsion. But with him it would be continued acting-out until a disaster, which is irretrievable, is precipitated.

One of the problems with this patient is, what can he see? In the consulting room the analyst can have an idea that what the patient sees must be much the same as what the analyst sees – so one would think. But either the patient cannot describe what he sees, what this experience is, so that the analyst is able to understand what he is able to see, or he is unable to see what the analyst sees because he is seeing something different. He cannot in fact be seeing something entirely different; he is in the consulting room and the analyst has no reason to doubt, therefore, that the patient is able to see, hear and smell much the same kind of thing as the analyst can, because they have both come to the same consulting room at the same time. There must be a certain similarity between what the analyst sees and what the patient sees. In that case, why does the patient not say something, or make noises, or make signs which indicate that he and his analyst have the same experience at the same time and in the same place? The possibility is that for some reason so far undemonstrated, in addition to what the analyst sees (not instead of it) the patient sees something else, hears something else, feels something else. What is this patient seeing, or feeling, or apprehending? It is reasonable to suppose that he sees, feels, apprehends at least two different stories at the same time. The same fifty minutes, the same consulting room, the same day, he sees the same thing as the analyst, but he sees, he apprehends something else which is different. If it were a question of visual sight the analyst could say, "You have put two different slides into your projector at the same time, so you get a confused image". He seems to be having an experience which differs from the analyst's experience. One could account for that by saying, "Well, the analyst is one person, this patient is another. Therefore, they don't see the same thing, any more than one person on one side of a mountain sees the same thing as another person on the other side of the mountain." But this, again, is a pictorial method of talking, or even a pictorial method of thinking. As far as one can tell, when this patient says he is confused it could be comprehensible if he saw or experienced two or more experiences at the same time and at the same place. If he tried to say what he is experiencing he would either have to invent a new language, which would be incomprehensible, or use a language which says two different pictures at the same time. In so far as the analyst is capable of understanding what the patient is talking about, he likewise gets an impression of two or more different stories about

the same fact and at the same time. Assuming for the moment that that is correct, what is the analyst to say to the patient? This is where the practice of psychoanalysis is so different from the theories about psychoanalysis. (It is also a situation which, if the analysis is still going on, raises the problem of the wisdom of talking further about this case in a meeting, not in the intimacy of psychoanalysis. Indeed, the whole problem of the scientific meetings of psychoanalytic societies is implicit in this particular question and answer.) I do not know what the analyst is going to say, because the language the analyst has to use was not invented or manufactured for the purpose of analysing patients. The language that the analyst has to use is the language of ordinary conversational communication which is useful in everyday life. But it is not appropriate for purposes of having an analysis. Anyone who had never heard of psychoanalysis would say of the analyst and patient, "There are two people having a conversation – simply one person talking to another". But there is a good deal of reason to suppose that a psychoanalysis is a unique experience. What is to be done about that experience? What language is to be spoken in the course of analysis? What was Aristarchus to say about his guess that the world goes round the sun? What would he have said to an ancient Egyptian who believed that the sun goes round the world, underneath, and turns up again on the other side next morning? *He* had to wait two thousand years for someone to invent a telescope. What is the analyst to say if he has to wait two thousand years to give this patient an interpretation in the correct language?

I believe that if I listen to this patient, if I am prepared to hear what he has to say, if I am prepared to see what I can see if the patient comes to me, then, although the patient cannot understand what I say to him if I am using ordinary language, he may be able to understand the meaning of the fact that I have not run away, I have not shut him up in a mental hospital and I am ready to arrange to see him tomorrow. None of this is expressed verbally, but it is possible, nevertheless, that the fact that the analyst has stayed in the room so far and will probably still be in the room tomorrow, may itself constitute a language which the analyst does not understand, which the patient does not understand, but which the two people together will have to make explicit. If that is right, then today's session, tomorrow's session and all the other sessions which have yet to happen, may have an effect on the patient. If the analyst is prepared to listen, have his eyes open,

his ears open, his senses open, his intuition open, it has an effect upon the analysand who seems to grow; the session provides the mind of the patient with what, if it were a matter of physical experience, one could say was 'good food'.

The analyst also has to be able to tolerate ignorance – his own – and his being in the presence of a mystery, a half-truth [see p. 48 – Negative Capability]. This seems to make it possible for the mind to have an experience in which it can grow. If the baby has a mother who is able to tolerate being frightened that the child is dying, or that it is mad, or stupid, then the baby seems to feel better for having such a mother. If she cannot tolerate it, neither can the baby who consequently seems unable to grow mentally. If it is going to grow it has to do so in a peculiar way; this, in turn, has the effect of making it grow a certain shape. Later, someone will say, 'psychotic', or 'schizophrenic', or 'borderline case' – it sounds just like a diagnosis.

But can the analyst tolerate growth? Can the community tolerate growth? Can a nation tolerate growth? Or does it get so frightened of it that it has to say, "Thus far and no further. No more progress please. I don't like it"? Or can the nation, or the group, or the individual say, "I'll put up with it. I can tolerate watching something grow"? It is not a brilliant achievement, but it does include the risk that the growth is pathological-mentally carcinogenic. That possibility contributes to the frightening quality of the analytic experience for both parties. That quality contributes to the need to prove that the analytic development is benign. It also contributes to finding a mental drug which may enable analysts to go to sleep no matter how dangerous the situation.

7

The following true story illustrates a number of points with which we are probably all familiar, and may get more familiar as time goes on.

I was asked to see a young man of twenty-one who was said to be very intelligent; not much the matter with him and probably a suitable case for psychoanalysis. A psychiatrist friend who knew him also spoke highly of him; although he seemed recently not to be fulfilling his early promise, he was most amusing, entertaining and, once again, just the person to profit by psychoanalysis.

The mother of the patient was opposed to psychoanalysis which she felt was unnecessary. She said that her son had always done well, there was nothing much the matter with him and she disapproved of this process of psychoanalysis. But she did not maintain her objections.

The father did not hold with psychoanalysis at all. He felt it was one of these fads which, like most fads, young people wasted time and money on instead of getting on with their work; he thought the boy would be better employed getting on with his university career.

Most people who knew him, or knew of him, also agreed that he was very amusing and on one or two occasions, notably on his twenty-first birthday, he had made witty and amusing speeches. I agreed to see the patient who was then just over twenty-one.

He was, indeed, co-operative; he missed no sessions and spoke freely. He said he did not get on well with his sister who was, in his opinion, a terrible liar.

I had occasion, before he came for analysis, also to see the sister who spoke freely, easily and intelligently, and told me a long story about herself and her educational achievements; she was two years younger than the patient.

The father asked me on one occasion what I thought of his daughter. I said she seemed to be a gifted and interesting person; whereupon he looked at me as if he thought I was what he expected – and that was nothing welcome. It was clear that he thought me an awful fool. When he was leaving he said, "Doctor, you realize, don't you, that this girl hasn't spoken a word of truth from start to finish – the whole thing is a fabrication". He obviously felt that I must be a fool not to have realized that none of this story was true.

The father also told me that his son was about to get engaged to a girl of whom he had a poor opinion. He said, "I hope you will be able to put an end to all that nonsense. You can take it from me that this girl is a bad lot and is out to get his money which she thinks he has a great deal of. As a matter of fact, he hasn't got a penny and I don't intend to let him have any, because I don't think he is at all sensible. I have had this girl watched by a private detective agency and they have given me a report on her which confirms my worst fears." I said I was sometimes not very convinced by these detective agency reports. The father thought this was also pretty stupid of me. I said, "The detective agency knows that you are suspicious of the girl and it is very easy for them to find out plenty of facts which would make you anxious, so that you would be likely to want to go on employing them". He was disturbed by this statement, but then dismissed it as probably being nonsense.

The patient told me that he was not in the least interested in this girl and had no intention of having anything to do with her. At the same time he thought that she was a nice girl and would be a good sexual partner.

I had a letter about this time from a friend of the patient, who said what a good fellow he was and he hoped I would help him because he was in great trouble: "he has so much money that he has lost enormous sums in each year of the two or three years that I have known him".

By this time I was beginning to wonder who was talking about what. I summed up the situation to myself as being one in which, to use the English expression, they were all 'off their heads', but I had no idea which head belonged to whom. So I settled down to listen to the patient's story.

It seemed coherent; he occasionally showed a lot of animation, but said nothing particularly witty or funny. He said that his sister was

hostile to him and disapproved of him because he liked the smell of faeces. As the analysis went on he used more and more vulgar words and expressions which are not usually used in polite conversation. I asked him whether he spoke like this to everybody, or only to a person like a psychoanalyst. He said he saw nothing wrong with that language and he *liked* the smell of faeces. He became indignant about it – "I *like* the smell of faeces; I think it is nice". I pointed out that we did not know why he came to see me, and he said, "I thought you knew. My difficulty is that I blush terribly. I thought you would have noticed it by this time." In fact, he was always pale; I never saw any colour in his face. He said that it was extremely painful – so painful that he hardly dared to appear in public anywhere and had, in fact, recently given up going to see his friends, or going out with them.

Somewhere towards the end of the first year of analysis – I was seeing him five times a week – he started mentioning that he had been drinking at the fountain. It seemed a strange expression, but I put it down to his being by way of a poet and a writer. From time to time he repeated that he had been drinking at the fountain until, to confirm my suspicions, I asked him, "What do you use for a fountain?" He replied, "Of course, an ordinary wine glass". It emerged after a time, bit by bit, one part of sentence one week, another part of the sentence a week later, another part another week, that what he was doing every time he said he was drinking at the fountain was drinking his urine.

At this point I wondered what kind of desirable, witty, intelligent, co-operative patient I had; and what it was about this patient that made him have no difficulty in using these unconscious (as I thought then) motives and methods of behaviour; why it was that this patient had no difficulty in understanding what I would consider was incomprehensible unless one was familiar with psychoanalytic theories. In short, this patient had no difficulty about psychoanalytic interpretations, but could not understand what we ordinarily call conscious speech. If he was to understand conscious statements he would have to get to them by a process which was like analysis; but whereas ordinarily I would expect to have to interpret ordinary English language to find out what the psychoanalytic interpretation was, with him I would have to translate ordinary psychoanalytic interpretation to find out what the fact was.

At this time the patient lived in his room behind drawn curtains, and had so arranged things that nobody ever called him on the telephone because it disturbed him that people could come right into his room through the telephone and interrupt the peacefulness of his life. That was the way he liked to live: he liked faeces; he liked urine; he liked living out of reach of anybody in this dark room. He explained that he could not bear being called on the telephone because he always became so terrified that it must be bad news.

I would have liked to say, "If you arrange that nobody should call you on the telephone, naturally you would think it was very bad news if they did; naturally you would be frightened if the telephone bell rang". It would indeed be natural in those circumstances to be terrified of the telephone, terrified of what he would hear, and most anxious not only to be blind, to live in the dark but also to live in a situation where he could hear nothing. But I said, "I think that you are able to hear my interpretations, but I don't think they mean anything". "Yes, that's right, that's right. You're quite right" he said, "they don't." I said, "I think that you are really not liking being alive at all and you are wanting to feel that you have gone right back into the mother's inside, in this dark, smelly, dangerous place in which there is no good milk, or good food; only faeces, smells, poison". "Yes" he said, "that's right." I thought, how satisfying it would be if I were a good analyst and if I could be right. But I don't think I'm right; I don't think that this patient needs to be fed on psychoanalysis – not by me. I also discovered that the patient did not want to be got rid of by me. I had that patient for the rest of my life; he was not going to stop coming to me. Why he was coming to me I did not know. Perhaps he liked analysis because it was such a dirty subject, such dirty language, such filthy, poisonous stuff but I did not know.

On one occasion, while seeing another patient, there was a telephone message for me. I said, "Call again later". "No doctor, this is urgent. Do you know anybody by the name of Mr XT (my patient)". "Yes." "He has just met with a serious accident crossing the road. Will you come and see him?" "Yes I will – later. I am busy. I will see him later". Here was my dilemma: If I, as a doctor, would not see that patient anybody would say, "This is a very funny kind of doctor who won't go and see his patient when he has had a serious accident". On the other hand, if I went to see this patient I knew he would be furious

with me for interfering in his private affairs. He did not consider it was any of my business to interfere with the way he lived, or with an accident if he happened to have one. I found out from him later on what had happened. He had wanted to cross the road, so he crossed the road. It was very busy and a car that was coming was unable to stop and knocked him down. I pointed out to him that he felt that if he wanted to cross the road he need not bother about the traffic or other people who were using the road – he could just set off. "Yes" he said, "that's right. Why not?" In short, he did not differentiate between the world of fact and the world of nightmares. He did the same thing in real life as most of us would do if we were fast asleep and having a nightmare. He did not have nightmares; he behaved as if he were living in one. He lived in a world in which chairs, tables and so on were what we should ordinarily call the furniture of a dream; but the furniture which you would expect to find in a dream was the furniture of real life.

Another occasion: The telephone rings. "Are you Doctor Bion? Do you know Mr X?" "Yes" "This is the police. We have this gentleman locked up in our cell. Will you come and fetch him?" In this way I was prevented from thinking about other patients, because I was always expecting the telephone to ring with a fresh piece of news about Mr X. Of course, I could cut off the telephone and darken the room, not see anything or hear anything, so that I could devote myself to him. Who was analysing whom? Was I curing him, or was he curing me? I do not tell you the answer, but leave it for you as an exercise in conjecture – you may have such an experience in your practice. Perhaps your friends or relations will say you are such a good analyst – they have just the right patient for you: young, witty, twenty-one, intelligent, just your 'cup of tea'. Such is fame – for psychoanalysts. I used to wonder if I had chosen the wrong job; if I might not have been better off as an ordinary doctor. But ordinary doctors have the same kind of patient. Ordinary fathers and mothers have the same kind of children. Ordinary sisters have brothers like that. Ordinary brothers have sisters like his sister. They all come to psychoanalysis in the end. If we live long enough, and if psychoanalysis lasts long enough, there will not be any shortage of patients. There may be a shortage of cures, and psychoanalysis may get a bad reputation because we mix with such extraordinary people, and because we treat them in such an extraordinary way that any father or mother would disapprove.

So long as there are psychoanalysts and psychoanalysis there will be no difficulty in finding somebody to blame.

I was able to draw the patient's attention to the feeling that if he became important enough, if he became a famous patient, then at last he would feel that it was worth killing himself if enough people knew about it. I could imagine that patient saying, "But I *like* murder; I would like to murder myself; I would like to be there and see the funeral". One day I received a message: the patient had left his room and had been found dead in the fields some twenty miles from London.

I cannot say that I felt I had done well. On the other hand, I cannot say that I even felt sure what the mistakes were that I had made. But I certainly could not believe that anybody would regard that as a satisfactory analysis of a witty, intelligent, clever, co-operative and friendly young man.

Q: Do you normally ask your patients questions, or just wait for free associations? What do you do when relatives of your patient want to speak to you? When a patient has to go into hospital for a time, do you yourself visit him there, or do you suggest that someone else should do so – for instance, a psychiatrist with some psychoanalytic knowledge?

Bion: In the practice of psychoanalysis it is difficult to stick to the rules. For one thing, I do not know what the rules of psychoanalysis are. There are plenty of people who will say "Don't you know the theories of psychoanalysis?", and I could say, "No I don't, although I have read them over and over again. I now feel that I only have the time to read the very, very best psychoanalytic theories – if only I knew what they were." However, that is what I would try to limit myself to. The practice of real psychoanalysis is a very tough job indeed. It is not the kind of thing which should be chosen as a nice, easy, comfortable way of life. Theories are easily read and talked about; practice of psychoanalysis is another matter. If the analyst engages on something that is not psychoanalytic practice, there is no one to take his place as the practising psychoanalyst. I would ask *any* question if I thought I was likely to get an answer. I would not expect to get any information from the patient I have been talking about – or from his father, or mother, or sister. Psychoanalytic knowledge can only be obtained psychoanalytically. Other information, however important,

cannot be substituted for psychoanalytic discovery. There is nothing that can substitute for what the analysand and I are able to discover together, however inadequate. The analyst must discover what the minimum is that he needs for his way of working; what anyone else needs is irrelevant.

There is a thing known as 'classical psychoanalysis': the analyst has an analytic situation in which he practises analysis; he has patients who are suitable patients and gives them suitable, certified – correct interpretations. I have never known that state. The analytic situation is the situation which the particular practitioner finds is adequate for himself.

Sometimes the seriously disturbed patient can tell me something which is important; sometimes he tells me the right thing by accident. But it does not matter whether it is on purpose or by accident if I am wiser for the information. I remember talking to a veterinary surgeon and saying, "It must be very difficult – your animals can't tell you anything". He replied, "Well, luckily they can't tell me any lies either". Silence, either of analyst or analysand, is golden – depending on the capacity of the pair to use it. A Brazilian analyst reminded me that sometimes there are patients who can be silent in five languages – it is well worth remembering.

Visiting, or not visiting, the patient is governed in principle by the conditions I have adumbrated; the particular application of the principle can be decided by no one except the practising psychoanalyst at the time. Practice depends on practice.

Q: You have said that an analyst can observe silence for a long time and feel differences between one silence and another. How can one compare today's silence with that of another day when one is working outside memory? Can it not be done only be setting aside that other rule which you have recommended?

Bion: I strongly recommend you to 'forget' that rule. It may stop you from using your intelligence. It is much better to use such intelligence or such wisdom as you have.

My patient did not need to be told not to use his memory. He drew the blinds, he arranged that nobody would talk to him and that he would not listen to his analyst's interpretations. In the end he found *the* cure – he died. And after that, as far as we know, he could hear

nothing. But that is a drastic kind of treatment and a very definite ending of the session. If one has a prejudice in favour of continuing to be alive, then you are bound to have difficulties and you are bound to find it difficult to follow any rule. All that you can hope to do is to use such experiences as have worked with you. I do not mean, therefore, that psychoanalytic training is not helpful, or that childhood is not helpful, or that your mothers or fathers cannot tell you something that would be useful. But the time for learning anything is so limited, and you are likely to waste it trying to be just like a grown-up, just like all your brothers and sisters, just like everybody else; it is protective colouring. There is no practical solution to the problem unless analysis finds it.

Q: If a teaching analyst, who has been inadequately analysed, has a candidate in analysis, and this person in turn qualifies and eventually becomes a teaching analyst, the standard of psychoanalytic practice is, of course, certain to fall. What is your experience or knowledge of this situation in England and the USA?

Bion: I remember a case in which the parents who were liars and drunkards had a most charming child who never ceased to make progress. I would hesitate to recommend drunken parents for everybody. Why the child did so well is a mystery which I still do not understand, and even if I could hear all the masses of psychoanalytic jargon which is freely available I still would not know the explanation. Conversely, a patient whose environment appears to be nearly faultless, may seem to have learnt only the expertise which makes it possible to destroy the favourable circumstances. Though I have no scientific basis to answer the general question which has been posed about England or the USA, I suspect that the particular instances to which I refer have a wider application.

Freud never suggested that dreams are good things, or that anxiety is a good thing; only that if you carry out certain procedures it is possible to make good use of a dream – the dream itself is not good; it is not bad; but some people can make use of it. Adverse circumstances are not good; war is not good; peace is not good; they are neither one thing nor the other. But some people make good use of the experience. The sooner we can learn to make the best of a bad job the better; analysis has to be done in this real world, for good or ill.

Q: In the case you cited, the analyst's role seems to help the patient to die, since he cannot help him to live. What do you consider to be the analyst's role in present-day society, from the point of view of helping to live or die?

Bion: The analyst's function is to psychoanalyse. It can be like being a mirror held up to the patient which would help him to see all of what he looks like. In accordance with what I have just said, I hope that instead of being 'just like', both parties might start 'becoming'. Trying to teach the patient psychoanalysis or psychoanalytic theories is a part of education, not psychoanalysis. If the analysis effects an introduction of the patient to himself it seems to initiate 'growth'. After spending their life up to date trying to be 'just like' somebody else, we are suggesting that they should be themselves, whatever they are, because they may have some redeeming features.

8

The confusion which I described in lecture seven is such a prominent feature of human activity that we shall have to discuss the matter further. First, we must beware the danger of prematurely seeking a solution which would remove from discussion what may well be an essential feature of human mental activity. The discussion is not intended to terminate, but to illuminate the object of the discussion. As an analogy, it would be dangerous to substitute a portrait for the person portrayed.

The situation I want to describe, using the ordinary time-scale of weeks, months and years, is somewhere between the ages of sixteen or seventeen and twenty-three or twenty-four: Putting it in more pictorial and less mathematical terms, the period of adolescence. But the term 'period' falsifies the situation by simplifying it. I am trying to consider a state of mind which is in no way pathological, in no way diseased, and in no sense stable, although disease and pathological events may be a part of the 'phase' studied. I can imagine that a time may soon come when there will be no general psychoanalysts, only specialists in some particular aspect of psychoanalysis, such as particular phases to which particular psychoanalysts are appointed. But to use these categories and fail to observe that they are related to the limitations of the human mind, and not to the limits of the subject studied, contributes added confusion to the confused situation. This is particularly so when we have to study the human personality. Analogies taken from anatomy and physiology may illuminate, but cease to do so if their character is not observed.

There is no realization which approximates to the verbal description of this phase of turbulence. For example, in adolescence the turbulence occurs when the personality is still enough of a child to

remember what it feels like, and is already grown up enough to suspect what it feels like to be grown up. Although we do not show signs which are anything like the gross transformations which occur when a tadpole turns into a frog, there are periods of transition which are much more marked than the periods in between. We can talk about pre-, post-, or delayed adolescence, and each division can be broken up into finer and finer subdivisions. These temporal subdivisions are survivals of a previous culture, as in the sixty-minute hour, or the three-hundred-and-sixty-degree circle. You cannot recognize when one minute transforms itself into another minute – not unless you have a look at a watch or some piece of machinery of that nature. In psychoanalysis, equally, you cannot see any of these divisions unless you look at something like a psychoanalytic paper or book. Reality is much more confused and there are no signs that the human being has devised to which reality approximates; the only certainty is that the signs denote a human characteristic. Yet a fruitful source of confusion arises from the failure to discriminate a peculiarity of the human mind from the reality in which we have our being.

Freud has mapped out a great number of characteristics and periods which can be seen to be recognizably human, characteristics of a human mind and a human personality. That very work now makes it possible to see certain periods in greater detail. Practical analysis is what I would call actually experiencing some period or state of mind of that kind, either one's own or that of another person who comes to share the analytic experience. A person in the adolescent period experiences survivals of childhood thoughts, feelings and ideas which have not died. They are vestigial, but they survive with a great deal of vitality. In language, a wonderful invention as Freud supposed, there are vestiges of its generation. Grammar displays some of these: for example, metaphors. Some are dead, some are still alive. If someone says, "I smell a rat; I will nip it in the bud", those are two metaphors, both all right in their context, but bring them together and these dead clichés, these dead metaphors, become alive and the result is ludicrous. Some of these dead or dying states of mind survive with sufficient vitality to sort [to correspond or agree with] well, but some do not sort with coming states of mind, post-adolescent states of mind which are also coming alive. So what with the states of mind which are supposed to be dying, and what with the states of mind which are supposed to be coming into existence, a

confusing situation is produced. It is not easy to say whether the state of mind at which we are looking, or which we are studying, is falling into decay, or is coming to maturity. That is what makes a period like adolescence so difficult both for the adolescent and for the observer. The observer (analyst) is in a peculiar position because he is supposed to remain stable, to remain in the same universe of discourse and to use the same language, and if he says he is speaking metaphorically he is expected to use metaphors which are coherent in that particular universe of discourse. He should not be like a musician who writes down the music but does not indicate that he has changed the key; the 'change of key' in discussion should be indicated. The analyst should be able to say, "I am not talking about surgery; I am not talking about religion; I am not talking about art – although all these may be used by me in the course of my talking. I am talking about psychoanalysis."

Unfortunately we have to use the already existing language. We may use the word 'envy'. People who are not psychoanalysts are sure they know what envy is; people who are psychoanalysts are not so sure. I thought I knew what psychoanalysis was twenty years ago; today I know too much to know that, or at least know enough to know that I am ignorant. I do not advertise it too much, not least because if I do somebody who thinks they know more, but does not, will usurp the vacant position.

Someone says, "I know what envy is; I know all about envy". But do they, one wonders, know what psychotic envy is? Or, to fall back on medicine to provide a metaphor, do they know what sub-thalamic envy is, or sub-thalamic hate, or infra-thalamic, or ultra-thalamic? I am here and now improvising a language with which to express my thoughts and ideas. It is difficult to express what I am trying to convey, even in the privileged position of being able to address myself to people who are familiar with the world of thought; people who may be analysts, psychologists, artists, or musicians, but who are all familiar with some aspect of the functions of the human psyche. The analyst who tries to pass on his knowledge or experience to someone else always runs the risk of that person saying, "I can't bear this nonsense; I'll shut my ears", or "I can't stand this stuff; I'm not going to any more lectures, speeches, psychoanalysis and so on – all psychoanalysts are mad". However, we have to put up with being accused of knowing nothing whatever about our subject. Unfortunately, it is very nearly true – but not quite. I suspect that we are not

in fact unique in this matter, that if we could establish a contact with the reality of, say, medicine, we might say that if you need a doctor the outlook is black indeed. You will find plenty of people who are qualified, who are entitled to the label, entitled to have the name, but there are very, very few doctors in reality. There are many people who have been to art school and have a degree or a certificate, but there are very few artists. Once in a while there is a Picasso and he runs the risk of being exiled from his country; it is an accident if some outstanding artist survives and continues to be able to live in the world as it actually is. The work that has to be done by psychoanalysts is, therefore, of the utmost importance, because if it is not done the individual will not survive. The crisis is there whether we recognize it or not. It may appear to be calm and simple like a latency period, or childhood, but if an analyst has a close look at the latency child with such intuition and intuitive apparatus as he has, he will see that the latency child already has the germs of being pubescent. I do not know whether you could say the same thing was true of the infant, but the expression, "the child is the father to the man", is certainly succinct: the child is never wholly a child; there is some aspect of the child which can already, to an observant, trained eye, be seen to be grown up.

We are already being forced into studying only a small part, a short period of the human mind. I say 'short', but it is not short or long, although it has some kind of dimension. After qualification we can set out to discover who we are and what we can do; all of us can mobilize that aspect of our personalities which comes easiest and most naturally to us, and thereby be led into a domain to which we are peculiarly suited. Then our troubles start, like a tennis player who goes to a professional coach, when he has finished his training he is nearly as good as he was when he was a natural player. But he may be potentially able to become better and he may be able to discover, shall we say, that he has a strong back hand, and he will use that against his opponents. Similarly with the analyst: when his training is finished he can begin to learn who he is and what he can do. It may take a long time – hopefully not too long. We live only for a limited period so that it is a matter of some urgency. After a time people learn what we can do and come to us; we get the kind of practice to which we are adapted and to which we adapt ourselves.

I would like to stimulate in you the idea of exploring one of these nodal points to which you could give a name – like adolescence, or

puberty, or latency. The advantage of picking on something like adolescence is that the adolescent has a lively sense both of the past and of what is coming. That is why adolescents are afraid they are going mad, or afraid they have got stuck, or afraid that they do not want to have anything to do with psychoanalysis, or afraid that they do not want to do engineering, or afraid that they are 'homosexual' – one more recruit for jargon. This period of turbulence is often detected by people who are not psychoanalysts. They say, "This boy (or this girl) is behaving in a very odd way; these adolescents are tiresome people – most worrying, but it's adolescence". Or they may say, "It's only a child", but nobody is only a child. There is no grown-up who is so grown up that he is not a child still. There is no child who is not part adult already. The human being is physically mature at an early age, but I do not think we would agree that the individual is psychologically or mentally mature at that time, or that that stage could be said to end at a particular point. It would be premature or precocious of us to say that the mind ceases to grow at the age of eighteen, or at forty, or fifty, or sixty. At the age of eighty it becomes more plausible; it seems reasonable to say that the person has just about finished, or has already declined mentally. But it is not obvious that we know the date at which mental maturity has been achieved and that from that point on there is a decline.

Leaving for a moment this relatively simply state of adolescence, let us consider some time like (physical) infancy. Since infants cannot speak the kind of language we are used to, although they can make noises which are like adult speech, the specialist in infant mentality will have to be able to tell the difference between the infant noises which have no future and the noises which might turn into human speech one day. When you hear a baby scream or shout, you will have to be a specialist to say that *that* particular scream has no future to it, and *that* particular scream is turning into something. If we can develop our powers and capacity for discrimination we may be able to see, and to be correct in thinking that we can see differences.

In a melancholy passage from the memoirs of Max Planck, the atomic physicist, he says that he discovered that you cannot teach our contemporaries anything. Progress does not consist in their learning anything. What happens is that they die and younger people come along. This sad discovery of his is something which any analyst must be aware of.

Q: You have spoken of the problem of communicating with a patient, calling attention to the merits of telling him what he can understand. The analyst can often see that the patient cannot understand. How can one talk to such a patient? Is there some means of communication other than that of using the language we use?

Bion: I think there must be a way of doing so, but it is difficult to know what it is. Children certainly seem, sometimes, to understand what we are understanding. There is a story by Beatrix Potter, *The Tale of the Flopsy Bunnies,* about a family of rabbits who "were all very improvident and cheerful". Children seem to have no difficulty in being told that, and yet it is impossible to believe that the child knows what a term like 'improvident' means. In the same story we hear that "lettuces are very soporific"; it presents no difficulty whatever to children. What they understand by terms like 'improvident' and 'soporific' I do not know, but that story would certainly be wrong and the child would resent it if some simple word were introduced instead; these long words are part and parcel of the story.

But it is not all a matter of 'words'. From the point of view of the child there is absolutely no substitute for parents who have a loving relationship with each other. No amount of talk or theory is going to take the place of the parents who love each other. That seems to put something over to the child which is – to use some more long words – infra-verbal, ultra-verbal, pre-verbal, post-verbal. There is no way of describing what sort of 'verbal' it is. This language is communicated by what I have fancifully called 'beta-elements': something which is not words. What is the language which is not a verbal language? While the verbal gap between child language and words like 'soporific' and 'improvident' seems to be immense, the non-verbal gap appears to be very small or even non-existent.

The question posed may well be a starting point for investigation. It is an example of what makes the practice of analysis exciting.

Q: You have often referred in your seminars and supervisions to the importance of the patient's not missing going to the analyst's consulting room. You have also asked why the patient goes. Could you go into this more deeply?

Bion: Very frequently analysts seem to allow themselves to be preoccupied with why patients fail to come and thus do not recognize the reciprocal mystery – why they do come. The investigation should not

ignore either polarity. Sometimes patients keep on coming when one feels that it is hard to see that it is worth their while in time or money, but they must be getting something out of it, and they must think it is worth while. It is a fact which the analyst should never allow to disappear below his conscious horizon. It is absurd for analysts to talk about the hostility of patients and so on – we know there is plenty of hostility; but the surprising thing is that there is apparently such a great supply of friendliness. People actually do their best to co-operate. They get to the consulting room, even when they feel sure that they cannot do anything when they get there.

Q: I would like to hear more about your reference, during supervision, to the patient's perceptions of his earliest experiences, starting with birth.

Bion: I would like to be able to hear a little more of the subject myself. I can hear something of it by listening to what people who come to me for analysis tell me. It is a most absorbing subject, but I have neither the experience nor the knowledge to enable me to know much about it. I have no doubt that what we call autistic children are in fact children in a frame of mind, or state of mind, which we have failed to notice so far. It is as if we failed to notice that children are children, both grown up *and* inexperienced. In so far as I describe a self-contained system in those last words, it may also be a description of an autistic phase, as Freud uses the term 'autistic' [Freud, 'Formulations on the Two Principles of Mental Functioning', 1911b]. Such an investigation may prove the answer to the question.

As parents we often behave and talk as if we expected the child to know 'all about it'. "Can't you see", we say indignantly to the apparently naughty little boy or girl, "that that is very naughty?" No, they can't. They may have picked up a valuable vase and hurled it at the cat, or beaten the dog over the head with it and smashed it, but they do not see that that is 'very, very naughty'. They may be able to say that it is an extremely satisfying experience. It may not be very good for the vase, it may not be very good for the dog or cat, but the child can feel very much better after it has done it. The child can say, "Can't you see how nice it is to do this?"; the parent can say, "Can't you see how naughty it is to behave like that?" – no, they can't – neither of them. They are like two people passing each other and shouting across the gap, but one of them is going in one direction and the other

one is going in the other direction. (The psychoanalyst may observe a psychoanalytic 'Doppler effect' as they pass each other. This effect is what requires to be noticed.) The words are the same, but the meaning is different. "Very improvident and cheerful": mothers and fathers think they know what that means; so do the children. The words seem to be the same words, but again, the meaning is different. To say, "This is an autistic child", says almost nothing; it is very nearly, on the part of the grown-up, a noise which may turn into communicable words one day.

The newly-born child does not use any language that we know, but mothers are sometimes able to understand the language; the baby screams and the mother knows the correct reply. Sometimes it may be verbal; sometimes she may pick up the child and not say a word; sometimes she may say, "I don't know what's the matter with the child", and hand it over to the nurse, or even, one is sometimes afraid, to the psychiatrist or psychoanalyst. I certainly have no prejudice against psychoanalysing children, but I have a prejudice against the substitution of the analyst for the mother. They may be complementary, but you cannot substitute one for the other without a loss.

Q: You have warned us to use not only our eyes to see with, but also our other senses to detect, for instance, our patients' physical excretions. But even so we are still not sensitive enough, since our minds, and those of our patients also, seem to excrete things which ought to be sensed through organs we know nothing about. Could this be one of the mysteries we ought to focus our attention on?

Bion: I do not think that any analyst is improving if he loses his capacity for mystery, for unsolved problems. This is not only a long question, but I am afraid the answer is terribly long. I can give a kind of short answer by telling a story of a physician who had a beaker full of some substance which he showed to a class of students. "Now", he said, "it is very important that you should not be frightened of examining and seeing and testing and using your senses to find out what something is – even something like this. Watch." He dipped his finger in and tasted it; then he passed the beaker around. There were all kinds of ugly grimaces and looks of horror and disgust. The doctor said, sadly, "I am afraid that you did not observe that I substituted one finger for another". I do not know what the 'moral' of that story is, but my 'meaning' is in it.

9

Q: Why is so much emphasis laid on the analysis of envy, as if this were the earliest anti-life emotion; before envy made its deadly appearance in human life we had been sentenced to death for pride. If it is pride that is the basis of the extravagant and undisciplined desire for spiritual possession – and this desire is to be like God – why do we not look into the content of idealization which pride seems to be? Why do we omit to analyse boasting and vanity, described as two of the twelve degrees of pride?

Bion: I feel that the question itself depends on a certain cultural procedure about which I am doubtful. It seems to belong to the domain of a culture in which things have a beginning and a middle and an end; and an essential part of the same culture is a narrative account which also has a beginning and a middle and an end. I think it serves a purpose; indeed, we still talk a language belonging to the same kind of domain of verbal expression. But suppose one encounters some quite different form of expression. One could call it, say, the form of expression which is common to a Chinese way of verbalization using ideographs expressing ideas by graphic description. The direction from bottom to top, or from right to left, may be suitable for a mode of thinking which is fundamentally different from ours, but it becomes difficult to communicate when we are talking the language from top to bottom, or from left to right – or from pride to envy, or envy to pride, or sex to rivalry. In practical analysis the analyst may see which comes first – unless, of course, we defer to reality and wish to express an order, if there is one, which is general. There are disciplines which have satisfied themselves of the order. In the practice of psychoanalysis we are concerned with finding out. But the whole

question of logical thought has to be revised. In so far as we are still learning, what we know is open to revision. For example, one can say today that it is an erroneous idea to imagine that the sun goes round the earth, but it was 'correct' once.

Freud described the investigation of the human mind as an assault on the narcissism of the human being. Indeed, we may very much resent finding that the mind is deposed from the position of importance which we attach to it. We cannot help attaching importance to it; we are human beings; we are members of a particular kind of animal used to regarding itself as extremely important, and the human mind as an important part of the totality of the human being. It is a revolutionary change to suggest that perhaps it is not so important and that perhaps it does not matter that we are not even able to grasp the problems with which we have to deal.

The problems which reality poses can turn out to be beyond the capacity of the human mind; the human mind with its logical, scientific, religious, artistic capacity is not up to the problems which it has to solve. To depose the human mind from its position of centrality, from the supposition that the world of thought is homo-central, is a blow to the narcissistic beliefs of the human being. One could regard it as a situation in which we are sufficiently capable and advanced to grasp the magnitude of our problems, but not sufficiently advanced to know what to do about them.

This, I think, is the situation in which the autistic child finds itself. The phenomena described by people who have studied this problem could be explained on the grounds that the autistic child is aware of a universe for which its equipment is totally inadequate; the infant is somehow so highly intelligent that it is capable of seeing the vastness of its problems, but is without any equipment with which to deal with it. The human race may be reaching a similar point (but on a different 'level' of the helix) at which the relationship of the most gifted members of the race, *vis-à-vis* the problems, is analogous to that of the autistic infant; the most gifted, most capable of our thinkers may be baffled and inadequately equipped for the realities of the situation in which we find ourselves.

To revert to the question of whether envy comes before pride, or sex before generation. We know that the physiologist would regard generation and sex as contemporary. If someone believes there is a

beginning and an end, and finds it helpful, I know of no reason why he should stop believing it – until he finds a better.

To take another example: I have no objection to saying, "Let's get up tomorrow at sunrise". I do not believe the earth stays stationary while the sun rises in a certain position, goes round and sets in another. But I would not want to reform the ordinary way of talking. I still think it is useful for people like us. But on the other hand, I would not advocate the abolition of heliocentric astronomy on the grounds that it is in conflict with geocentric language of getting up in the morning. It is a useful language for certain simple purposes, but unsuitable for more complex situations such as the launching of a space probe through the atmosphere of Jupiter, through the close contact of Mercury, and then on still further into space to investigate the nature of Saturn. There must be mathematicians who are capable of working out these (to me) incredible mathematical problems; *I* can be hard put to it to use ordinary arithmetic to work out a simple thing like the time it takes to travel from Rio to Los Angeles, or from Los Angeles to London. But someone is able to do these things and it is difficult to believe that that person's mind might be inadequate for the problems which are posed by the investigation of a thinking mind. I have no objections to classical analysis, or to the theories of Freud, Abraham, Klein and so on – not unless I am told I must think so far and no further. Trying to impose that kind of limitation would be as futile as telling the earth to stop going round and round the sun in this puzzling manner. The universe does not obey orders from anyone, however self-exalted. As I say, I have no objection to the ordinary method of talking or writing, but I have every objection to supposing that that method is good enough for our problems. Psychoanalysis – the best psychoanalysis – is not good enough. I cannot agree with anyone who says, "Psychoanalysis has been good enough for my analyst; it was good enough for my analyst's analyst; and what is good enough for my analyst's analyst, is good enough for my analyst's analysands" – and so on, until the mind dies. We may not know what sense is, but we often recognize nonsense.

If the first thing I am aware of is envying my brother or my sister, or their envy towards me, that is what matters to me as a practical baby. But someone else may find that the first thing they come across is something which is not envy or hate, but arrogance or pride. What

is the starting point of a circle? One can only say it is where I happen to be aware of starting.

Q: If 'getting better' in psychoanalysis depends firstly on integration, on synthesis of the personality, is the synthesis offered by the process of analysis enough, or must certain techniques sometimes be used to promote synthesis?

Bion: I could say, first question: why start with this question today? Why the second question second? Why not the second question first? Second question: why synthesis? Why not analysis? Why analysis? Why not catalysis? Or why not catastrophe? I do not know any reason why not. Except possibly something like the very, very, very unimportant answer, namely, that that is where the questioner started; that is what hit me first. Using more pictorial language, that is the point at which my young brother, when he was not much more of a baby than I was myself, happened to hit me on the head with a hammer, and I died – finish; full stop. Why or how we come to have survived so far I do not know, but since we have we can start our process of thinking anywhere between birth and the present. If the first thing you are aware of is arrogance, or the first thing you notice is murderous hostility, you can start the investigation there. But in infancy the first things to which we give names are those which are susceptible to our physical senses. For example, the infant becomes aware of the vast space, the incredible spaces, the incredible numbers; and then we discover that the vast spaces are only the boundaries between 'self' and the cot in which the baby lies, or these vast numbers are the name we give to a feeling of 'threeness'. The baby soon becomes aware of a stomach-ache but is not sure *what* is hurting it, or *who* is hurting it. Of course, if the baby is a thorough-going Kleinian it might say, "This stomach-ache is inside me", or it might feel it was being attacked from outside. Unfortunately we cannot ask the baby – not yet.

Q: As the founder of group therapy you have brought psychoanalysis within reach of many middle-class people previously unable to afford the high fees for individual analysis. Even so, there are still a great many people who cannot afford group analysis. Would you favour a socialization of psychoanalysis to deal with these people? To what extent does payment affect treatment?

Bion: It would be a great mistake to imagine that I originated group therapy. I come very far down the list of people who have engaged in group therapy long before it even had a name of that kind.

Would I be in favour of socializing psychoanalysis? In other words, would I favour putting the cost of psychoanalysis on a particular group or not? Who is going to pay for analysis – group analysis or personal analysis? Who is going to pay for having no analysis, group or otherwise? And what is the price of that going to be? Many people, whether they like it or not, will have to pay for there being no analysis (assuming for the moment that analysis is worth paying for anyway, in view of the cost in time and money and effort and all the things which are not included in the ordinary scale of measurement which is provided by a financial system). I could state the problem in terms of Péguy's approach. Referring to the French motto, "Liberty, equality, fraternity", he said that liberty and fraternity are in an absolutely different class from equality. Equality is mixing in an element which is of feeble consequence compared with the other two. People are not born equal; they start life with different equipment. Péguy pointed out that equality of riches and opportunity is hardly a social problem but destitution is. The fact that people are poor does not do much harm to the community, but destitution is more than an individual problem. A destitute person rots the society, the group; destitution within a group of any sort will sooner or later destroy that group. The social problem of destitution, therefore, should never be disregarded, should never be neglected. This is not socializing psychoanalysis; it is saying, however, according to Péguy, and I think there is a great deal to be said for his formulation, that destitution is already socialized; it is a socialized quality. I do not know what the benefits of socialism are, but as usual it is much easier to see what the liabilities of socialism are, particularly the socialization of destitution – that is something which no state, community, or group can afford.

I do not know how payment has an effect on the treatment, but I consider that the treatment ought to have an effect on the payment. That is to say, one would like to produce a situation in which, as a result of psychoanalysis, destitution was decreased; that people who were incapable of earning a living or increasing the wealth of the community, should become capable of doing so. John Ruskin said that wealth meant something like that which increased the health

and happiness of the community – the life-giving properties. It is the capacity of the group to produce life-giving material which should be increased.

Money is an invention which, like language, has been proved to be useful. How to use it has not yet been discovered. The present economic failure may convince us that it is time we thought about its use. If, in analysis, we find a way of making this discussion redundant we shall not contribute anything to the solution of these problems. 'Payment', therefore, may serve, as it is doing here, to stimulate the discussion. In this respect it is no different from other stimuli of which the participants become aware during the course of the investigation itself. What it costs you to read this book, and what it costs me to write it, can only be answered if there is a scale of measurement and facts to measure.

Q: Has the number of mentally-ill people increased, or are they only now being detected and treated as a result of therapeutic techniques based on psychoanalysis?

Bion: I remember one of the leading neurologists in England, at the time I was a medical student, not having the slightest idea what was the matter with a patient who was submitted to him, but a young medical student suggested that the patient was suffering from what is nowadays called myasthenia gravis. In the short space of my own lifetime myasthenia gravis has become a medical entity; it is a recognizable constant conjunction of symptoms like 'myasthenia gravis'. Most competent physicians would now hope to be able to notice if one of their patients had such a disease and could probably diagnose it. You would have to be unfamiliar with the world of thought to imagine that doctors have been guilty of increasing illnesses; they have only increased the awareness of the illnesses. If psychoanalysis did nothing else it would have done a great deal if it made people able to recognize the existence of certain constant conjunctions. There will always be people who hold us responsible for having *caused* neurosis or psychosis; that but for us no one would bother with the whole thing, and nobody would know anything about it. But there are many physical diseases which would gradually wipe out the human race if no one knew anything about them. As I said before, only a matter of a few hundred years ago people thought it was natural and normal to die at thirty. Why draw attention to something as normal as that?

Today people say, "Why draw attention to anything so normal as dying at seventy or eighty?" You cannot do anything about it, but someone may later. Somebody may discover a cure for myasthenia gravis which is better than administering physostigmine, which is not a cure, but relieves the symptoms. Medical advance is a co-operative procedure, not only amongst doctors, but between generations of doctors; if we can record our findings and pass them on, then in four or five generations when we are all dead, someone may learn something. But that depends on our having noticed something first – very unspectacular and most unlikely to make anybody famous.

Q: We live in a competitive society; the agitated life in big cities is the cause of neurosis. Might one say nowadays that everyone is neurotic, or is this an exaggeration?

Bion: We could say that all of us are neurotic, but is it worth saying? One could say that we are all human; that might sometimes be a useful remark, however inadequate. There was once a cartoon in *The New Yorker* in which one of the seconds in a boxing match said his man would not fight until he had heard the other one talk – his way of being quite sure that the other boxer was actually human. It provided a rough and ready test of classification. In the mental world we have similar problems. Will someone who is so intelligent, such a clever animal that he looks just like a human being, ever become human? Will someone who does *not* look like a human being – like the autistic baby, or the latency child, or the adolescent – become one in time? We need to know how to tell whether someone is becoming anything. Even in illness it is useful to know whether some cough, or ocular defect is the sign of the onset of disease. It must, however, be remembered that it could be the onset of growth. Our problem could be stated: can we discriminate between benign and malignant? Both possibilities have to be entertained. One idea has to be balanced against another. A one-track mind does not give practice to the driver in a multi-track world.

We do not know what mental disease is, except in the general sense of dis-ease, un-comfort. Psychoanalysts are people who attach great importance to happiness and consider that unhappiness can reach a point which could be called destitution. That degree of unhappiness could be regarded as communicable because it surpasses the confines of the individual; the lack of happiness becomes so great

that quantity changes into quality. We should support or provide for the destitute, the person whose unhappiness has reached the end of the spectrum.

The question pre-supposes that the problem is a topographical one, that it is due to competition and rivalry. But if there were no rivalry that again would become a growth-inhibiting disease caused by a lack of stimulation. Similarly, the human unit, the couple, depends for survival on a relationship between the two parts which is self-propagating, growth-stimulative. On the other hand, in the individual, or group of individuals, destitution is inseparable from greed. The extremely wealthy man, who can be seen to be greedily wanting more wealth, shows himself to be destitute.

Q: According to Freud the experiences of life in infancy are important in the formation of the adult; from these come in great part social, sexual, emotional, economic adjustment. What advice would you give a mother so that she can bring up her child free of repressions and inhibitions which might provoke neurosis later on?

Bion: There was once a joke in *Punch* magazine: Mr Punch's advice to those about to marry – "Don't". I feel rather like that about this question. I would be inclined to say to the mother, "I think you had better not have a child". I would hate to live in a world which was peopled by individuals who had no repressions or inhibitions. This is one of the difficulties in analysis; people come to an analyst having already had a 'cure', and if the cure consists of their being incapable of repressions and inhibitions they are mutilated people. Any analysand wanting an analysis is already up against a problem, because it is not clear or certain that inhibitions and repressions are all bad. Supposing that we can interfere with this matter at all – we can also be interfering in the capacity to discriminate. Discrimination consists in being able to exclude the irrelevant. When that capacity becomes extreme it turns into an inhibition – the 'voluntary' has become 'involuntary'.

One can imagine what could happen if psychoanalysis was allowed to proliferate like a cancer – go mad, as it were. There is already a great deal of behaviour which is supposed to be based on psychoanalytic principles supposedly advocating no discipline at all. Anyone who has had an analysis knows that it is an extremely tough discipline. We do *not* advocate that people should come to have a nice time for fifty minutes a day, for five days a week, for five years.

We *do* try to introduce the individual to the fact that even if we did not exist they would have a feeling in favour of a discipline. One of the dangers of letting a child do just whatever it likes is that it does not simply do just whatever it likes. The moment it is aware that not even its mother or father can watch what it is up to all the time, and it is therefore free to do what it likes, the child at once and automatically reconstitutes the missing parent. You have probably seen one of your own children solemnly go and stand in a corner as a kind of punishment for some crime that we have heard nothing about. But that reconstituted parent has insufficient knowledge or experience to be a parent – it is simply part of the child. So that the failure of the parent to impose some discipline means that the place of a potentially sensible or wise person is taken by an inexperienced conscience and a disciplinary system which is so severe that the child may break down under its own discipline. A premature and precocious disciplinary framework produced by the infant who is not in the position to produce any framework is, possibly, part of the self-contained system which Freud called 'autism'. The result is a discipline which is so ferocious that the child cannot grow under it and would ultimately perish unless something were done to modify, but not abolish, that discipline. The personality or the group compelled to be 'autistic' is, therefore, liable to be dominated by immature and premature structures, with dangerous consequences. Unfortunately, however experienced we are we still know very little indeed about how to bring up children, of whatever age. We are beginning to know that we do not know – that is something. We are beginning to be able to plumb the depths of our ignorance, stupidity, bigotry, license, but it may take a long time before we know much about bringing up children – which seems an extraordinary thing when you consider that we do reproduce our kind. Sometimes we reproduce our own kind only too well – our children are exactly like us.

10

The tenth lecture differed in kind from the others. It could for that reason have been omitted, but I thought that, with added comment, some readers might find the account illuminating. The added material is marked with a line in the margin so that the reader can ignore it and gain some idea (in so far as the written word can transmit a live experience) of what an unrehearsed episode can evoke, to what further experience it can become an 'idea generator', and how he would deal with the same experience.

At the end I have added a few questions on which the reader can exercise his mind should he so wish.

PRESENTATION OF CLINICAL MATERIAL FROM PART OF A SESSION

Patient: I am not satisfied, I don't feel alive – although I pay for the treatment and play my part.

Analyst: You do not pay the price of tolerating the frustration which is part of life.

P: I used to dream that I was not born; the dream has become reality to me. (He blames his mother for having pushed him out. He speaks of a maid he has, who left a convent where she lived. He thinks she did wrong. In the convent everything was solved for them by God.) I had a job for six weeks. Why did I do this work, if I wanted to be dead?

A: You want everything in life without anguish.

P: Who conceived me with so little tolerance? This person must feel guilty.

A: Since you do not accept the blame you cannot feel alive.

P: (speaks of the rage he feels when thinking of the use of a cutting knife. Then starts to talk in a whimpering voice) You can't say that. How could my mother do this; I liked her so much. I'll never be right.

A: You see me as your mother who does everything.

> The analyst and patient are continuing a relationship of which I know nothing; the dialogue is new to me. Why does the analyst say this? Has he some first-hand evidence? If so, what? Or has he been told that psychoanalysts talk like that? Why does the patient talk like that?

P: (in a childish voice) I can't teach him. I don't know, it was so nice there; why did she separate me? When someone has a companion he thinks maybe the companion does not want him any more.

> Who is he 'teaching'? He is certainly not teaching me because I don't know what he is talking about, but I must hear some more.

A: What you are saying again shows your wish to be free of suffering.

P: I see a baby – myself at my mother's side, very happy. I see myself in a lake, on a plant, I'm in paradise. I don't understand why they threw me out. I know it is madness to think like this, but they threw me out. I was doing so well, why did they disturb me? Could it be that I awoke within my mother's womb? The scientists say we have no conscience. I think I am mad.

> What is the patient talking about? If he thinks he is mad he is probably suspicious about the nature of what he is 'seeing', but people often speak of having a vivid visual imagination – why does he suppose this vividly described story is not just the product of such an imagination? Perhaps the analyst will throw some light on this when he continues the conversation.

P: I awoke within the place I so much liked. I had no reason to be in a rage. I had little it's true; I didn't want anything. I had everything, love, security. One feels full, suddenly everything is over. I was angry with my mother because all was ended. How could it happen before

I was born? Is it possible to be conscious in that hour? Could it have been when I was born? I was conscious I was entering a world full of problems. My mother, instead of giving the best she had, was giving the worst. Small people already know everything. Later you forget. A small child knows more than an adult. The child knows that the first contact with life is the most important. The adult confuses things. We seem more conscious in childhood.

> Surely this is some story about childbirth that the patient has heard? Or is it some recent re-hash of so much 'psychoanalytic' fashion? The stuff about 'childhood' and the 'knowledge' of the child is suspicious.

P: At forty I am rebellious. I still speak of being born. I knew this on the first day; I don't need to live forty years to know this.

> This certainly sounds like sarcasm – if I were to tell an actual patient that, he would probably be 'righteously indignant'.

P: Today you told me that I have no tolerance for frustration and that must have happened on the first day. Crying the first day, my mother could have thought there was no motive for crying, for I had just been fed. But the fact is that I screamed, rebelling against being born. My mother becomes wicked, an egoist, beastly – I can't take this separation. You say that I could have, but I haven't, because I bestowed everything on my mother. I never thought I had arms and legs. Having these things, I never thought I could function by myself. Mother has – she functions for me. She says I oppose functioning, in spite of conditions. (He mentions his office where he has an assistant engineering designer whom he thinks of as the mother.) I don't need to do anything. He has to do everything. I know nothing; he is the one who knows; when mother (the designer) is present I know nothing. The analyst knows everything. I know nothing.

> This sounds 'genuine' sarcasm, but it is mixed up with bits of the patient's actual experiences and not just what he has read out of a book.

P. (He gives the impression of thinking about something which gives him pleasure.) It is very pleasant. Mother is a wrapping and

inside the wrapping it's good to be in there. It is much better there; mother's legs carry me; it's her responsibility.

> Chiefly what he has read in a book. But either the patient is playing a game with the analyst, or I am being made a game of for pretending to the knowledge of a 'lecturer'. But even a hoax can be interpreted. If I were analysing a patient I might have the conditions which would enable me to hazard an interpretation. No doubt he would like me to say it's a 'hoax'. Or if I did not, then he would think I was saying he is 'mad'.

P: When small, with the parents near, I felt no fear. There is tranquillity. I find this security wrong, stupid. When the designer says he has to sign some paper, he then asks who is going to break down the walls for the reconstruction (of a building). I don't want to have the responsibility of walls falling. That is part of the mother. This answer I myself as an engineer could give. I know more, much more than that, but I don't know. I don't accept doing it. Two plus two are four or not. I must exert myself to say that. It may be two or not. I had to struggle to reach that, which is so obvious. Really I'm going to remove the walls which are between the beams. The building is not supported by what I am going to remove. This is logical, but for me it is not logical.

> Another bit of 'truth'. 'Logical' is the way rational people talk and 'rationalize'. But this requires understanding by someone who is not restricted, 'imprisoned' in the logical modes of thought.

A: You reject that two plus two should be four, so what is correct and true for all the world is not true for you.

> I think the analyst is very near the patient's wave length; can his formulation be understood by the patient? His next remarks sound as if the patient was near enough to the analyst's wave length to erect his defensive barrier and to continue the communication. 2 + 2 isn't 'logical' mathematics, but two similar numbers get together. But 'he' never thought of that – too homosexual. Two homo-numerical is quite proper.

P: I reject that because I did not invent it. That is why it may be wrong. Someone discovered it and that someone could be wrong.

A: You feel it is the parents' mistake for having sexual relations. They should not have had them – because of this you are not able to gather together your pieces, for if they come together you will be full of hate and envy – you will be yourself.

P: Do you think so? I don't know, I never thought of sexual relations; what has that got to do with it? Two plus two are four, but I did not invent that. I did not invent sexual relations. They say it produces children – I don't know. I didn't invent it. I know it's stupid to think like that. I'm suspicious. I don't know of what; of a person's being able to say something that is wrong. They say that if you put one brick upon another you will make a wall. That might be wrong. I'm always in doubt; can I accept this or not?

> Is it creative? Or is it just a defensive wall? The patient would like to know – and so would I!

[*This concludes the clinical material.*]

Bion: What is this patient's problem? Why is he coming to see the analyst?

Presenter: The patient wanted treatment because he felt very isolated.

Bion: But there must be some problem about this; the patient must have some reason for coming to see an analyst.

> For example, if it is because he is lonely, merely coming for a talk acts as a 'cure' which, being ephemeral, has to be repeated; if repeated and if unobserved this leads to a never-ending analysis and ever-receding progress.

Bion: The question which confronts us is, what impression does this give you? What do you think you would say about the reasons for this person actually coming? Why should anybody want the analyst to see him?

We do not appear to know. No one has any idea how such a situation has arisen. What does this man want?

Q: I would like to ask your opinion about the client who gives a positive reason for seeking treatment, but whom the analyst cannot decide whether to treat in one interview, or the client who cannot

put his problems into words. I feel it is the business of the analyst to help the client to formulate and to know what he wants and what sort of treatment he needs. I think this is an analyst's responsibility.

Bion: I would emphatically disagree. All I purport to do is to have such training as I can get for the benefit of those who want an analysis. I can try to get a consulting room and the conditions in which to work, but after that I would certainly not be prepared to analyse whoever happens to come. I would have no right to analyse them. If I were asked to analyse them then I might try to do it, but it would be dangerous to start analysing somebody when you have not even been asked to do so. Anyone who comes into your office must expect to be asked to explain his business; it is not a public highway: it is a private room and if they come into it they must be prepared to say what they want. I would certainly not take the risk of starting to analyse and give interpretations to such a person. I should consider that I was liable at once to have an action for damages brought against me. It would be just as serious as a surgeon starting to operate on a patient without the necessary authority.

Q: The audience is in difficulties because you are trying to debate openly and frankly, and it finds itself in the position of the patient who says the only trouble with him is that he feels isolated.

> This is reasonable because it is not clear whether the audience has come for a lecture 'about psychoanalysis', a seminar on a psychoanalysis, a group therapy session, or an investigation of a particular psychoanalyst's (my) capacity as a psychoanalyst. All 'answers' are therefore ambiguous because it is a matter of ambiguity to guess what the question is that is being 'answered'.

Q: I remember a particular case from my own experience – the only case of this nature in my twenty-four years of practice. This patient, a woman, came for a preliminary interview, and I asked her why she wanted analysis. She said she had difficulties with relationships. "What does that mean?" I asked her. "What do you mean by that word, or those things? Can you tell me anything else?" "No", she replied, "Only that". I said I thought this was not much for me to assess whether treatment was indicated. I wondered if we could

work on the basis of so little information. She replied that she could not say more than that. I told her that I could do nothing on such a basis, since I could not understand why she was here. She said nothing, and I said nothing either; we found ourselves in a position similar to that here now, where both sides have fallen silent. After some time, about half an hour, I said, "I think we must close the interview. It seems to me that you don't want to be analysed; you don't want to, or cannot reveal yourself; on this basis I can't accept the job of doing an analysis. We must abandon the idea." She insisted that I ought to treat her. I refused, and closed the interview.

Bion: I am not surprised to hear it. In that situation the analyst would be running a very serious risk indeed. It may be very well for the patient to say, "It's your business to treat me", but it is not any doctor's business to be told by a patient what he must do, or how he should do it. If you feel willing to risk obeying the patient's instructions you can go ahead, but I would not do it myself. If I had a referring letter I would like the person who referred the patient to say why they were doing so, and what for.

Q: What about analysis undertaken to become a psychoanalyst? Is this not very like that case, where there are no medical grounds for having treatment? The candidate can take refuge in this idea that he wants analysis only because he needs it to qualify.

Bion: If the person wants to be an analyst I would suggest that they should go to some proper analytic authority or institute. If I were the authority I would say to the applicant, "Can you tell me on what grounds you are presenting yourself here as a candidate, and why you wish to be considered for the vacancies that we might have?" In exactly the same way, if I am in the position of an analyst who purports to analyse people, I would expect to be told by somebody, either by the person concerned or some responsible person, on what grounds they thought this person should come to me for analysis, or why they should think I was the person to analyse him.

Other analysts can do what they like about it, and I can see that they might handle the situation differently, but I cannot. I can only handle this case with such capacity as I have, and my capacities do not include a capacity to do what I call 'analyse' this patient. I do not suggest that somebody else could not analyse him, but I do know

enough about myself to know that I could not – not on those grounds. I would not be prepared to take that risk.

Q: I would like to re-read the first phrase that this patient said. "I am not satisfied. I don't feel alive." However, he said he would pay and do everything else he ought.

Bion: I would like to know what he is not satisfied about.

Q: He is not happy because he is very lonely, because he cannot communicate with anyone. He has no friends, feels unhappy because he is not taking full advantage of life, does not enjoy anything and so on.

Bion: I understand that, but I can say, "What do you expect me to do about it? If you aren't satisfied because you don't do these things, go and do them." I cannot do them for him. It is a fantastic situation – the patient says, "I am not satisfied because I haven't come here today"; I say, "All right, come here today then".

Q: Do you feel that if the patient could do it he would do it; he comes because he himself cannot do it?

Bion: Where is his nurse? Or where is the person who brings him? If he comes alone *he* is responsible for coming. He cannot say that he comes because he has been brought. If he has been brought I would say, "Let me see the person who has brought you".

Q: From what I understand, it would be enough, instead of analysing the patient, to tell him to do the things he finds difficult to do. This would solve everything. That is to say it is not accepted that the patient is unable to do certain things for deep, unconscious motives, or that he needs the analyst's help to succeed.

Bion: I do not admit that a patient who maintains the right to say he has come of his own free will cannot get to me. I cannot admit that a patient is entitled to say he cannot get to me while at the same time he has come. If he cannot do all those things I would say, "Who was it who brought you? Can you ask them to come in and see me about it." I have another example in mind. Suppose you were a pharmacist; someone comes to your pharmacy and says, "You are a pharmacist. All right. Give me those pills." The pharmacist surely has the right to say, "No, I'm sorry, I don't do that. I need a proper authority, a proper

reason before I can give you these pills. Otherwise I shall be in trouble with the law." It is true that you might be in trouble anyway. The man might draw a gun and demand to have the pills handed over. Why is an analyst any different in this regard? If someone wants an analysis the analyst can at least say, "No, I know something about analysis, and I don't do this to anybody just because they happen to want it, any more than I would hand pills to anybody who happened to want pills. I would need to be given authority to do it."

Suppose I launched out as it was suggested that perhaps I ought to do – started analysing – and found myself, the next thing, in a court of law. "But doctor, didn't you know that this patient had been to psychiatrists and analysts before?" No, I'm sorry, I didn't." "Did you find out?" "No, I'm sorry, I didn't. I just started analysing him." "But why?" "The patient said he wanted some analysis." The analyst is supposed to be a responsible person who does not analyse anybody and everybody.

Q: I cannot quite understand what it is that you demand when starting an analysis. Could you go into this further.

Bion: First of all I would want to know on what grounds the patient came to me for analysis. I would want to have some proper reason for analysing him. I do not know what other people do – in any case, it would not help me; other people are not me, nor are their patients my patients; but I do know something about myself and the risks that I am prepared to take. I am not prepared to take this one. Under no circumstances would I agree to analyse anybody unless I was given what I consider to be the minimum reasons for proceeding.

Q: Could you give an example of what you consider to be these minimum reasons?

Bion: I do not even know the minimum reasons for being a surgeon, or for being a physician, but I have a fair idea about what I am prepared to do, and I know that I would not be prepared to analyse this patient; not on the grounds of anything that has been said to me so far.

Q: If an adult comes to me and says he is in trouble, feels isolated, cannot make himself understood to others, is unhappy, cannot work, wants to better his life, and is able to pay for treatment, would you

not think all this was enough? I do not understand what is missing that is so important.

Bion: Nor do I. That is what I am trying to find out. But I do know that there is a terrible lot missing as far as I am concerned. Everybody else may be perfectly satisfied. They may feel they have all the information, knowledge and experience to proceed. It may be my experience that is missing. But I do know that it is missing and I would not proceed until I had more. Otherwise, it seems to me that one is in a position in which anybody is free, as soon as they are landed with a hopeless case and have failed to help in any way, to send him to an analyst. Analysts are there; they are a sort of communal rubbish dump for all the people, things, jobs that nobody else wants. I have nothing to say about other people who take on the patient, but I would not.

Q: From what you say and what I understand, it seems impossible for anyone to be treated by you. But you still seem to have patients. So it is my impression that you are not telling us exactly what you demand, what this element, this condition is, for someone to be your patient.

Bion: I do not see 'patients' – I see particular individuals, and when a particular individual comes to me I want to know what he has come for.

> I do not ask him, as I have just been asked, to tell me exactly what he wants, but if he will tell me in the best and simplest – not the longest and most complicated-way, I will do my best to understand him.

If the particular person is of unsound mind, or not of age, then I would want to know their parents, or their nurse, or their doctor; perhaps they would come to see me and tell me what they want me to do. If the patient is totally irresponsible I would like to see a responsible person. I am not going to risk my whole career and my professional reputation by taking on a case about which I am not told the minimum of information. If the doctor thinks that this patient is a suitable person for me to analyse I would say, "Can you let me know what makes you think so?" Any doctor would have reason to be ashamed

of themselves if they sent a patient like that to me without a covering letter, or without a nursing attendant. If I were given adequate reasons for analysing that person then I might try to do so. But there is nothing, so far, which would lead me to suppose that there is any excuse for this person taking up my time.

Q: You have talked about mystery in these lectures. I hope you are not going to leave us with this mystery which I feel we have now. I do not understand what the conditions are which you, not we, lay down before you take on a patient.

Bion: Which patient? If you do not tell me which patient, it is you who are leaving me with a mystery.

Q: I feel very much in accord with you, but I should like to know more about my own reasons. Referring to the patient you talked about in lecture seven, you interviewed the father, the sister, had a letter from a friend and a recommendation, I suppose from a colleague, maybe a psychiatrist, to attend this patient. Was any of this information of any use? The sister lied, the father told the story of the girl friend which the young man denied. In what sense was this information used? Did it help you to decide to take this patient into treatment? Did he come alone? What care and attention did he have?

Bion: The thing that helped me to take that patient more than anything else was sheer ignorance and unjustified daring. My qualifications for seeing that patient were precisely nothing. After seeing that patient and realizing what I had agreed to, I think I was a wiser man. I did not want another one of those. There was not a single one of those persons whose statements could be relied upon. The only thing that could be said about analysing such a person was that the analyst who did it was extremely ignorant and foolhardy.

Q: I should like to state what I feel are the conditions you hope to find in a patient to enable you to treat him analytically. Today's patient seemed only to complain. In a case of mine the patient did not wish to exert himself; in another, the patient was satisfied to remain a fetus. I suppose that a minimum requirement, besides the patient wanting to be analysed, is that he should wish to analyse himself too: to work with you.

Bion: I am sure that the minimum conditions vary immensely, but I do not know what they are. I do know what they are with me, but not with other people. I cannot tell other people what the minimum conditions are for them because they may require far less in the way of conditions than I do. But I can know when a situation which is developing, or has developed, is one which is beneath, as it were, the threshold for me. There is everything to suggest that it is a miracle that this patient, having reached years of adulthood, is still in existence. But nothing in the course of that life has done him any good. I would like to know on what grounds it is supposed that I could. The most exalted surgeons, physicians, psychoanalysts, psychiatrists, might all know that they could treat that patient, but I know that I could not – not so far – not on that amount of information, or with that amount of co-operation. That does not come up to my minimum requirements. I do not want to have my career cut short at any time. Something of this kind happened in an actual case in England. A member of the Board of Control – a position of considerable prestige – was sued by a paranoid patient and had punitive damages awarded against him. He was, in fact, ruined by that case. As a result, no doctor in England would certify a patient under any circumstances. The law courts, the parliament, the lawmakers had to think again, because doctors were not feeling that the minimum conditions in which they could do their job were in existence. They were being asked to do things which might leave them and their families ruined. What were their minimum conditions? I do not know, but I have no doubt that those doctors did know. It was too dangerous to have anything to do with paranoid patients. But you have to examine a patient before you know whether he is a paranoiac, and the conditions for examining such a patient did not exist, because nobody was prepared to put themselves and their families at risk. Sooner or later, somebody will have to think again before they decide that psychoanalysts are people on whom you can put any job which no one else can do, and at which nobody else has succeeded. In my opinion this is one of them. This patient is dissatisfied, according to him, because he does not do what he has to do. I cannot do it for him. If he is not prepared to use the knowledge he has, what is the good of my giving him any more?

Q: A patient, referred to you by someone, comes to your consulting room; he says he wishes to have treatment – perhaps become an

analyst – because he has difficulty in tolerating himself because he is a pervert, having committed atrocities against others. Would this case be within the minimum condition of acceptance?

Bion: There is nothing that you have told me about this patient so far which would make me hesitate in taking on that patient. I might be entirely mistaken just as I might be entirely mistaken in saying that I would not take on the previous patient. No one can tell me – it is even difficult for me to know myself – whether the rewards are adequate. We are faced with a similar though more extreme problem in the process of getting engaged or married. You can say, "Well, so far he seems a nice fellow, or a nice girl. I wouldn't mind our going out to dinner together." That might ripen or develop into a situation in which you proposed to each other that it would be a good thing to make it a more permanent arrangement. "Will you promise to go on having dinner with me for the next fifty years?" is a tall order. Fortunately, the analytic relationship is only a temporary one; in intention, at least, it is to last only for a matter of a few years at most. Only the analyst knows how much he can stand of analysing a patient, or how much he can put up with that patient's behaviour.

Referring to the patient just mentioned: I would say, "If you wish, we can give analysis a trial". If the patient says, "Yes, all right doctor, I will. But will you tell me what psychoanalysis is?" I would have to say, "I'm sorry, I would tell you if I could, but I can't. There is no way of knowing what analysis is – with me at any rate – except by coming to me." But with the previous patient I could only say, "I'm sorry, but I would be asking you to waste your time to come to me. There seems to be nothing to justify the expense of your time and money." The trouble here is that we are discussing something in the absence of the patient. One is having to fall back on some idea of what it would be like *if* such a person came to us. Of one of them I can say, "That doesn't sound to me what I want"; of the other, "That one sounds possible".

Q: When I am practising psychoanalysis, although I do not deny the importance of environment and external circumstances, I try to show the patient that his recovery depends a great deal on his own resources. The patient's attitude has to be altered. What is your opinion on this matter?

Bion: That seems to me to be a perfectly fair description of the situation. We do not think we can satisfy the patient and we cannot foretell the future. But we can say, "Together, in this consulting room, there's nothing we can do about your circumstances. But if you think that you might change and become more able to put up with the world as it exists, come along and try." But the first thing they have to find out is whether they can put up with analysis. The first patient is asking the analyst to commit himself to behaving as if he can still do something for a patient who has already said, right from the start, "I can't put up with analysis. I can't even permit the analyst freedom to exercise his own judgement" – not so blatantly, but that is about what it amounts to.

QUESTIONS TO AID THE GENERATION OF IGNATIAN EXERCISES[1]

1. How would you differentiate (a) a lecture (b) a seminar (c) a group psychoanalysis (d) supervision (e) psychoanalysis (f) psychotherapy?
2. What is your opinion of the patient described? What would you say to (a) him (b) his dependents?
3. What is your criticism of the 'lecturer'?
4. How would you have dealt with the situation had you been (a) the lecturer (b) the audience (c) the patient, if you heard your analysis had been discussed in a meeting?

1974 SÃO PAULO

1

The urgency of our work forces us to discriminate. We therefore have to consider only such topics as appear to be most economically relevant. Our problems more than keep pace with such progress or advances as we make. If one tries to match oneself against these problems a critical situation becomes more and more critical faster than we are able to develop our techniques and our ability to deal with it. We need some quick and efficient method of recording what we do – assuming that past experience would add to our store of wisdom. Not so many years ago people who wanted analysis seemed to have plenty of time and money with which to meet the requirement of the situation. Today even governments of states are confronted with problems which are beyond their control, or their capacity. Consider something which was once regarded as a simple matter of mechanisms of exchange and economics: when I was a small boy I once discovered a coin in one of my pockets. I had no idea that I was so fabulously wealthy – it not only made my day for me, but the next day too. Nowadays we feel well off at one moment; at the next our valuables have seeped away from our 'store'. It appears that even states experience this descent from affluence to poverty.

As for the emotional forces with which we, as psychoanalysts, are concerned, we can discern the same phenomenon in mental or psychological terms. The spirit of the country swings from a sense of affluence to a sense of bankruptcy. Which are we to consider the 'generator'? The economic situation leading to recession, or the emotional situation leading to economic recession? We, who purport to study the motions of individuals, need to state the 'direction' which the progress is taking, but we have no co-ordinates by which to indicate this primitive base. The subject becomes even more harassing in

a state of emotional turbulence. We shall have, later, to investigate the turbulence.

With regard to our mental resources, one would like to believe that we have enough knowledge or experience to run our lives in a rational manner. I wonder, in fact, how many people feel that they know how to deal with today's problems and the problems which we shall have to face tomorrow. All this seems to point to the urgent necessity to limit our analytic activities to the absolute essentials. We cannot say that everybody needs analysis; even practically it is out of the question, for our resources of time and money are limited – not only the physical resources of the earth which are now seen to be exhaustible.

Provisionally our solution will be to consider the essential problems of the patient who we shall see tomorrow, and go straight to the central point of those problems with as little dispersion of our capacities as possible. We are limited to this as we are only psychoanalysts, and not because we are unaware that our contribution is only to a minor part of a minor part of a vast domain, or because we think our importance is in any way comparable to that of our leaders.

Our psychoanalytic philosophy is based on respect for the individual. The anatomical and physiological aspect is clear to us, but is it accurate to imagine, for example, that I am these hands? Where does my personality end and someone else's start? Where does the analyst come to an end? And where does the analysand start? Where does the individual and particular become the general and non-specific? What are we to say about a mental discipline? If we were athletes we should have to be able to run, or swim, or play games and so on. But what games are we to suppose that a psychoanalyst ought to be able to play? What mental diet are we to regard as being productive of mental health? (Later we shall have to discuss what mental athletics are necessary for those who use their minds.) These questions at once confront any authority who is concerned with an institute of psychoanalysis. We do feel the need for some kind of common language; we should like to be able to talk to other analysts from any part of the world. But should any one of us be able to talk to someone who had learnt his psychoanalysis from the time of Homer? Our education tends to teach us that the works of Virgil, Plato, Milton and so on are simply beautiful literary works of art. But I do not think that that is what they were written for. It is very difficult to get past this screen

which obscures their original purpose and meaning. It will not be long before people do not understand what Freud was talking about. Can you know what you yourself were driving at in notes written six months ago? What is the message that Henry the Navigator would bequeath to us by his voyages? Historians of human thought can only conjecture. The problem is further complicated if we cannot even pass information on to each other. In trying to teach our sons and daughters something we think they ought to know it is extraordinarily difficult to know how to remind ourselves of what we were like when we were twelve or thirteen, and to believe that our passionate feelings of love for our boyfriend or girlfriend were somehow inferior to our capacity for passionate love after we have been married ten, twenty, thirty' years.

What do we investigate in 'psychoanalysis'? Do we simply want to be able to say to someone, "Ah, you will be wiser one day – I used to think like that once", or would the young version of ourselves say to our grown-up selves, "You have turned out as badly as I thought you would"? It is difficult to be sure that we could maintain that we have improved. Analysis makes it possible to reactivate the thoughts and ideas and feelings that we had once, and bring them together with the thoughts and ideas and feelings that we have today. With the patient we 'see' tomorrow our concern is a mystery, not that which we know. An 'ordinary' conversation is, and can be recognized as, a 'mystery'; it is rash for analysts to talk as if they had, or could, plumb that mystery, and a falsification to think we approach a problem that has already been solved. Analytic experience is a disaster if the human being becomes indistinguishable from a watch, or a computer, or any other machine. It may be appropriate for a child to talk to its doll or its blanket and feel that it has company. It is inappropriate for psychoanalysts to be so frightened of real life that they do not talk to each other, but talk jargon to a 'construct'. There is no future in being just like an analyst, or just like a grown-up. Our problem is not what tomorrow's patient is just like, but what they are becoming.

We may now discuss the turbulence to which I referred earlier. Adolescence is not a disease; it is a time of such mental turmoil that a great deal of which we are usually unaware comes to the surface. The analyst should consider whether the adolescent' is waking up, or growing up. He should, in spite of all the news about the dreadful things which are happening, be able to come to a correct assessment

of what the situation is. You may feel, from your own experience, that the boy or girl is in danger. On the other hand, you may feel that they will come through the experience more grown up, more responsible. The analyst is expected to pronounce on this situation. "Well doctor", the parents say, "what do you think of him?" It is a dangerous situation because analysts are supposed to be able to give an answer which is closely related to the facts approximating to some psychiatric or psychoanalytic theory with which one is familiar. But the facts that he sees may not be the ones to which the questioner is referring. One should be able to say something like, "I think it is possible he might benefit from analysis", or, "I don't think I would advise you to try analysis for him just now". But we may not be able to say what we think, because the parent, and still more the boy or girl in question, would not be able to tolerate the information that we have to give. An extreme possibility, such as suicide or murder, may be clear enough to be discernible, but in real life even extremes are not 'extremely' discernible. A patient may say he has terrible nightmares, but passes it off, saying, "I'm not really worried about it – I know they are only nightmares", or you say to him, "I hear you said you were going to murder your young sister". "Oh, that! I was just joking." It is probably true, but on the other hand he may not be in a position to know about these 'jokes'. The youngster who has just been teasing his parents by saying he is going to commit suicide, likes to believe that it is just a joke; the parents likewise. The psychoanalyst does not believe that this story starts at the age of eighteen, and knows that some of these 'jokes' have to be taken seriously. "But doctor, surely you don't think he ought to have analysis five times a week" – and you have to say, "I think it would be just as well, if it is possible. It might help."

Q: Your reference to the question of taking notes reminds me of your teaching regarding the analyst's working without memory and desire. There would seem to be three types of memory: first the dream-like memory; second, that which comes rapidly or suddenly into a session; and third, a memory or conscious recollection of the past, of some analytic experience. Your comments would clarify this for us.

Bion: Clearly, unless one used one's memory or desire or ambitions one would make no progress. During the session the patient's difficulties do not stop; he is still fully aware of his difficulties and of his

need to have attention paid to them. It becomes a serious matter if the analyst is present in mind but preoccupied with trying to remember. 'Trying to remember' is, in my opinion, being 'analytically' essentially absent. It is precisely during this short fifty minutes that one should not allow oneself either to 'remember', or to 'hope', or 'wish for', or even to 'understand' what the patient is talking about. Therefore, the analyst may not be able to make notes, but he should be able to 'make the notes' essential for psychoanalysis. I cannot offer any suggestion as to where or how these notes are made, but in my experience they are made. I have previously pointed out that I do not know where the parallel lines of a railway track meet when one sees that they come together in front of the observer, and behind him if he looks back.

I look forward to reading a paper by the questioner investigating these different forms of memory; I hope to use his categorization when they have been clarified – for example, criteria for discrimination of an hallucination from a dream. These problems cannot be investigated in books, or scientific meetings, or in the presence of the analyst's conscious theories. That is why I deprecate memory, desire and understanding *while the analysis is going on.*

2

One technical term which is often used, and probably abused, is 'counter-transference'. It is a term which should apply to the unconsciously motivated feeling which the analyst is having about the analysand in the analytic situation. The term should be correctly used, as should all terms used by the psychoanalyst. This is not a pedantic matter; it is dictated by the fact that our chosen tools, as it were, are words. If we use them wrongly we soon find ourselves in the position of a sculptor using a blunt instrument.

Someone mentioned to me a boy patient who 'doodled' on the table as if he were writing or drawing. The analyst might find it worth while doing something of this kind on paper dating it, say, April 15th, and putting it aside. Then at a later date, say, May 1st, instead of looking at notes made in a more conventional manner, one could write down one's interpretations of the squiggles or marks made on April 15th. In that way one can make use of one's conscious activities of May 1st to interpret the unconscious productions of April 15th. Drawing upon his own conscious and unconscious, the analyst would not be confusing two different analytic procedures; they are both recognized frames of mind and there is, therefore, a technical disciplinary framework.

In contrast to this there are analysts who carry their professional activities into their homes and cause a great deal of trouble by interpreting in psychoanalytic terms the behaviour of their families. I am not suggesting that we should stop being psychoanalysts, but while you may have some psychoanalytic idea in your mind about the behaviour of a son or a daughter, or a husband or a wife, you do not *have* to interpret them. If I started interpreting the behaviour of members of my family I should certainly be afraid that the family

was being deprived of a father and getting an analyst instead. That may be a lucky thing for the family – or it may not – but giving psychoanalytic interpretations is part of one's professional life; there is no harm in that, but there is great harm in depriving a family of its father or mother. The same thing applies to professional activities; we should not confuse analysis and supervision. If you are supervising it is important to make a sharp distinction between the conscious activity of supervising the candidate or analyst, and analysing him. If you start analysing him when you are supposed to be supervising him, you deprive him of his supervision. You are also interfering with his analysis and his analyst. The failure to consider these problems is causing a great deal of trouble both to the psychoanalyst and his family, and to the psychoanalyst and his colleagues. This is not a theoretical idea; it has been forced on me by what I have been able to observe for myself.

Q: I would like to hear your opinion about the question of the importance of supervision in the development of the young analyst.

Bion: In the course of our professional life we can see very few personalities. Indeed, we meet relatively few people in a life time; but that situation can be to some extent corrected by activities such as seeing plays, reading biographies and reading fiction. Perhaps I should say "reading other works of fiction besides biographies". As analysts we must be aware that accounts which purport to be portrayals of reality are, in fact, the writer's interpretation of reality. This kind of reading provides a wider experience than we can have by learning only from those few people we manage to meet. Much the same applies to scientific meetings and supervisions; you can get an idea about how other analysts work. You are not obliged to say whether you regard the scientific papers as works of fiction or not. But you can form some opinion of the kind of fiction that those particular analysts write, or the kind of reality which they describe. In this way you can augment the small amount of direct experience. I consider there is a place for meetings and discussions *about* psychoanalysis provided we are not misled into thinking that they *are* analysis. Psychoanalysis is a unique experience; it is, therefore, a serious deprivation if the analyst or analysand makes the mistake of thinking that it is just an ordinary conversation. In a certain sense so it is; but if it is experienced it is both an ordinary conversation and a unique emotional experience.

The importance of supervision consists in the degree to which a peripheral activity augments the centre of the activity. Its negative contribution is proportionate to the extent to which the periphery has usurped the place of the centre.

Q: Is there any use in recalling a session in order to discover what prevented the patient from seeing something of the emotional experience?

Bion: Trying to recall that experience is not the same thing as an experience which obtrudes spontaneously. Suppose you say, "That reminds me of a dream I had last night". One could say that at one moment there is no memory of this dream; at the next moment the whole dream is present. When you start recounting it you take time over it, and it has a beginning and a middle and an end. But that is not what it had when you said, "That reminds me": the beginning and the middle and the end apply to the conversation – not the dream. The more familiar we are with the domain of mental life, the more we become aware of these subtle differences. It is worth while, therefore, having respect for the 'way' in which we think or dream.

Too often the individual objects to awareness of some event; hallucination is one notable example. Bigotry and intolerance emerge as defences against the unwanted event. The 'denial of sex' was one of the most striking examples in Freud's psychoanalytic discoveries.

Q: Could you speak about the feelings in counter-transference which are dependent on the feelings of the patient: in other words, the influence of the transference in the counter-transference.

Bion: They are very much the same as the influence in the transference of the presence of a psychoanalyst and the effect that it has upon the patient. The conditions do not exist for doing anything about the counter-transference. In contrast, the analyst can try to analyse the analysand's reaction to his, the analyst's, presence in the room.

Q: You have referred to the analytic experience as being unique. Do you consider that the emotional experiences we have all the time have the same characteristic?

Bion: I think they must have, otherwise the emotional experiences of the analysis are of no consequence whatever. Our theory is that it is worth bothering about what happens in the consulting room and

in the relationship between analyst and analysand, because we think something similar probably happens elsewhere. In analysis we can try to discuss it; elsewhere we cannot. If you can say to a patient, "You are feeling that I am angry with you", that may be true but it is of no importance. It does assume a certain importance if the patient feels that much the same kind of experience to which the analyst has drawn his attention happens in any number of situations outside the consulting room. To put the same thing in different terms: psychoanalysis, however wonderful and however erudite, and however brilliant the analyst or analysand, should resemble real life. Putting it differently again: if someone draws a picture and says, "That's what my wife looks like", one should be able to feel, "Yes, it looks human – I've seen people like that". Of a drawing by someone of the stature of Picasso we might say, "Yes, I think I know what he means – although the person in the drawing appears to have three eyes and two noses. It may not be much use to a surgeon, but perhaps it does matter to a psychoanalyst. This may not be a good drawing if I want to know how to dissect out a seborrhoeic tumour from the face, but it does teach me something about human beings." Similarly, you might say of a play, "I think people do behave like that". The fact that Shakespeare wrote it does not matter; what does matter is that it reminds you of human beings. In the same way psychoanalysis cannot be any good unless it reminds you of people.

Q: In the counter-transference situation the analyst uses his own models to deduce the model that the patient is using. This we do in order to avoid theorizing, but every model used suffers from transformation. After some time the model may not be useful any more, no matter how creative the analyst may be. Instead of getting another model would it not be better to use another kind of system of investigation?

Bion: I think it would be better to get another analyst, because the analytic interpretations which are stimulated by counter-transference have a good deal to do with the analyst. If the analysand is lucky they may also have something to do with the analysand. Sooner or later, an analysis which is based on the counter-transference will come to disaster, or at any rate failure, because all the interpretations will have little to do with the analysand and a great deal to do with the analyst. In physical medicine this would become apparent fairly

early if the surgeon operated on the strength of counter-transference and not on the strength of the anatomical and physiological findings. Unfortunately, that is not unknown. We, as analysts, try to avoid it.

Q: We should like you to say something about groups.

Bion: The kind of experience which one has in psychoanalysis – when there are two people present in the room at the same time – can seem to happen where it is a relationship between a whole lot of people. For example, just now a number of people laughed. They must have had the same experience, or so one would think; all those people who laughed experienced the same emotional experience at that moment. If that is the case, can a single person like myself here, or any other single person in the room, say they have an idea of what the interpretation would be of that laugh? This is typical of an unspoken interpretation of 'the group'. One would have to develop a sensitiveness to what seemed to be the emotion common to the majority of the group; the group analysis would have to depend on the assessment of the 'gist' of an obtruding emotion. It bears a similarity to psychoanalysis, but it is not the same thing.

Groups are sometimes structured; the psychoanalytic institute is typical of the 'structured' group. In group practice I used to try to avoid structuring the group so as to leave any structure that might exist a chance of emerging spontaneously.

3

Q: The psychoanalytic institute here recommends that students should study Kant. Possibly this results from something you have written in which you refer to Hume and Kant. Would you clarify for us the relationship you see between certain theoretical formulations in relation to the problem of thought, and the works of Kant.

Bion: Kant was attracted by the fact that people think and that we do not all think in the same way, nor do we all see the same phenomena. Philosophers are curious about thought itself.

Most activities are apparently self-explanatory; even in extremely primitive times there was an awareness of the existence of something 'not self' and a curiosity about this other object; the self also obtrudes into consciousness and adds to the non-self experience. Objects which are not oneself can become names with the names which we ordinarily associate with things. Sometimes, in the course of analysis, one becomes aware that the analysand has had, and is still having, difficulties which appear to be associated with an awareness of himself. In practice the analyst can suspect that this difficulty, although discernible today, must have been apparent to the patient long before he can have had any equipment adequate to deal with what he was aware of. Our problem today is associated with the detection and comprehension of symptoms or signs of that awareness. You need hardly doubt that any analytic belief that that is happening would be sure to be both controversial and difficult.

If you watch a baby lying in the cot sucking its fingers or thumbs, or – that extremely admirable athletic ability – pushing its feet into

its mouth, do you think the baby might be experiencing embryonic, philosophical conjectures about its experience? Assuming that one does think so, in our hypothetical 'tomorrow's baby' are there vestiges of such a preoccupation? We know what a stir was created by Freud's suggestion that there was such a thing as infantile sexuality. We can scarcely hope to escape similar controversy about any suggested extension of 'infantile mentality'.

Q: In your book, *Attention and Interpretation,* there is a difference between the liar and the thinker. I would like to hear more about truth being independent of the thinker, and the lie needing a thinker.

Bion: In so far as we understand facts, it is evident that the fact does not owe anything to us at all. But a fabrication by the individual concerned is a different matter. If one simply tells another person the truth about some phenomenon such as where a pencil is, that is not a particularly exciting discovery or statement. But if you tell them where it is *not* and you see the individual concerned engaged on a wild hunt for the non-existent, that is a creative effort. You can see children's excitement and pleasure at having made an April Fool of someone. They learn at the same time that it is a matter of consequence as to whom you make a fool of, because grown-ups are such unpredictable, dull people who do not think it at all funny. So the process of discrimination arises in the course of activities of that kind. Waging war, or just arguing with another person, is helped and furthered by deceiving that person.

When we hear the patient talking to himself, is he trying to help himself or the analyst, or trying to deceive himself? These primitive activities have not disappeared from the realms of human behaviour. One still finds it useful to help somebody by informing them correctly so that they could further one's own aims or objects. The distinction between the lie and the truth, and the uses of both those kinds of communication, are borne in on the human being. This kind of activity has precipitated the preoccupations of philosophers who regard accurate thought as of first importance. Today, when it is not clear that man's wisdom has increased in proportion to his physical power, the psychoanalyst has taken over the responsibility for extending the philosopher's approach to clear thought.

Q: You have spoken several times about things 'never being the same'. Can there be a difference more convincing than that between a dream and an hallucination, between a dream as an association and an hallucination, and between a dream and a lie?

Bion: Those are certainly important distinctions, but I would not give them priority over other differences if and when they are observed. The point I meant to make was to emphasize that 'things' do not remain the same; history does not repeat itself. It is always new.

The child who bumps its head on the table is interpreting correctly when it hits the table; later he hits someone else. Today we are attempting to achieve a different approach. The 'difference', when we wish to establish our own responsibility for our own pain, is very great because it is fundamental.

Q: Due to insufficiency of alpha-function there are sensitive elements in an excessive number which disturb mental life. This is corroborated in recent studies in experimental psychology and neurophysiology; also the studies on the average evoked responses, evoked by sensitive stimuli on the EEG. Such studies show that in paranoid schizophrenics we often meet a predominance of the articulate attention; the attention tends to select some sensorial data and to focus on them. The same studies show that the opposite happens with non-paranoid schizophrenics. In the latter we may conclude that there is an insufficiency of alpha-function, a great number of sensory elements not selected and not elaborated. I should like to hear you speak, first, about the progress that psychoanalysis has been making on the study of the alpha-function, chiefly on the alpha-function on paranoid and non-paranoid schizophrenic patients; second, about the implications of such progress on the concept of the paranoid-schizoid position which appears to be adequate for the elucidation of the paranoid states, but inadequate for the elucidation of the schizomorphic non-paranoid states of mind.

Bion: The problem which has been stated has itself been one which has to be expressed in terms of such language as is available. As far as I am concerned I have to pay attention to a pattern of sounds which are made by somebody who is not me, and

I have to wonder what the pattern of sounds means. It is indeed very difficult. Part of this can be simply and obviously explained, but all those parts of the problem which are obviously and simply explained are hardly worth bothering about. If they really are obvious and simple, what is the problem? But as it is, the problem is difficult to state with the existing language, and the person who formulates that question is liable to be ignored on the grounds that we do not know what he is talking about. That is a simple answer, and an entirely useless one; it may indeed be dangerous if the problem that is stated, however inadequately, is in fact a serious problem. As I say, all this could be explained on the grounds that I do not understand the Brazilian language. But that is not really the problem. I do not think any amount of understanding Portuguese would get me much nearer to answering the question. For example, the speaker said, "Studies show". At this point I feel, according to the language that I talk, studies show nothing. One can look at these things, one can listen carefully, and if one is lucky one can see a kind of verbal pattern; but after that one has to interpret the study. It is extraordinary how many people think that we have learnt something when we see a smoke drum (a drum covered with smoke-soot – on which a pattern can be made) or, to use some learned language and long terms, 'an encephalogram'. I am sure that makes everybody feel a lot better. Ah! Here is something scientific! Here's the graph. Look at it! It so happens I have nothing in my hands. . . . Very often one cannot have anything which is so consoling as an encephalogram, especially when it comes to the human mind – you cannot smell it, see it, touch it, or say what its shape is. Then how do you know there is one? Nevertheless we go on behaving exactly as if there were people who have minds which we can interpret. While no one in Homeric times seemed to think there was such a thing as a mind, or a soul, or a spirit, they had no difficulty in believing that, say, Agamemnon had appeared to them in their dreams – they did not doubt the validity of that dream. In fact, it was a great deal easier for them to believe in the interpretation of a dream than in what an actual, live person told them. There is nothing new about the interpretation of dreams.

I would like to consider briefly the problem of the use of a language which is totally inadequate when applied to states of mind

and mental pain. The language of physical medicine is now becoming, for us, more of a nuisance than an asset. At certain stages like adolescence, infancy, middle age, old age, certain discomforts become apparent to the individual; he does not like what is going on and will want to fall back on the idea that it is just like some kind of pain he is used to – there is always consolation in feeling that we are familiar with and know what we are talking about. But explanations made in rational terms limit our freedom and exclude consideration of the irrational and an approach in which logic and logical thinking may be irrelevant. Our preoccupation with books and discussions may itself be a sign of mental turbulence in which we participate without any appreciation of the forces that draw us together as if we were puppets without awareness of the puppeteer.

During periods like adolescence there is a great deal of turmoil. I have to talk about turmoil, whereas an artist like Leonardo can show his preoccupation by producing many drawings of turbulent water, or hair. What he was preoccupied with we cannot now possibly know, but one could say that he could draw a line round it. I have deliberately picked on adolescence because we are all familiar with that sort of upheaval; we probably remember it in our own lives. But there are numerous other ages like latency, infancy, and the number of these 'names' is increasing all the time. Not so many years ago most people would not have heard of autism. Even we who have heard this term might be hard put to it to say what it means. However, there are psychoanalysts and others who have become curious about a constant conjunction – a state of mind becomes sufficiently noticeable for one to feel that certain features are constantly conjoined. But we do not like coming across something which is novel and which we do not understand; we are bound to want to feel that we know what we are talking about, so we fall back on the old, well-established clichés – "This child is ill", "This child is seriously disturbed". It is doubtful that there is any evidence for those statements. Unless we are tolerant of our ignorance there is no hope of doing anything about it. If we are patient enough, tolerant enough, we may be able to look at what frightens us, and although we may still not be much wiser we have to put up with that. We have to start by tolerating the fact that we

are extremely ignorant; we have to come off that particular perch hitherto occupied by homo sapiens and consider the possibility that our ignorance is so abysmal that even the autistic child might teach us something.

4

When we give an interpretation in response to the patient's free-associations it is not the same thing as transforming the free-association, and yet it could be said to be not very different. Is it really an interpretation, or are we transforming what the patient says into something entirely different? Freud considered that a great many ordinary sexual facts, with which everyone is acquainted, are treated as if they do not exist and then transformed into all kinds of phenomena which are said to have nothing whatever to do with sex.

It might be worth considering another phenomenon with which we are all familiar, that is, money or mechanisms of exchange, the exchange itself being a kind of transformation. If you have money with which you buy a car, or a house, or landed property, it could be said that you are transforming your money into a car. If you buy an analytic session you could say you are paying for so many minutes of a psychoanalyst's time. Judging by the present day economic chaos, workable exchange mechanisms seem to present difficulties for the human race. An adequate currency is essential in commerce; it is no less essential in language. Psychoanalytically the *in*adequate currency is our preoccupation – not what works, but what does not work. We have to be adequate psychoanalysts, but we do not have to be unaware of our inadequacy; admiring established so-called 'classical' analysis is not part of practising psychoanalysis.

The Babel myth is a good description of a way in which an almighty god can create such chaos that people cannot even cooperate in the building of a tower. Different languages make it difficult for one nation to talk to another – a matter of importance to us who would like to feel that analysts throughout the world could talk a common language. Mathematicians have not achieved this.

Intuitionism is still controversial; so is quantum mechanics. I hope it is true of psychoanalysis. I have not been convinced that our capacity for controversy is yet adequate – 'no' is not an argument against 'yes'.

We have a sophisticated mechanism of exchange, but this does not mean that it is adequate. Primitive language is often highly complicated *and* inadequate. Highly complicated, sophisticated psychoanalysis deserves scrutiny, but not awe.

The infancy of money, cowrie shells as used in religious and other activities, has been taken over, but its use for the purpose of commerce has been obscured by its worship and by the awe with which its devotees still regard it. In short, its 'infancy' survives today when its 'scientific purpose' has been submerged. Often this is easier to observe in a group than in an individual analysis. The two modes of observation are not exclusive; they could be complementary. "If he's content with a vegetable love, which would certainly not suit me, Why, what a most particularly pure young man this pure young man must be!" [Gilbert and Sullivan, *Patience*]. That sarcastic observation, divested of its sarcasm, might describe a recurrent emotional phenomenon.

It was the early system of religious exchange, bride-purchase and wergild [see p. 9] that was taken over by people who wished to make financial exchanges; if you parted with something valuable you were compensated by being given some money in exchange. Something which is consciously and rationally known and which is governed by apparently rational laws, is in fact closely geared to emotional experiences of the utmost significance-like marriage, death, murder, religion. That is tapping very powerful emotions. The financial chaos which threatens to overwhelm the whole of economic commerce may be being influenced by deep emotional forces which will never be approached by any rational, economic conference.

Coming back to what the analysand is paying for: we do not know why anyone asks for an analytic session, nor do members of the public know why someone says he or she is an analyst. What is the mechanism of exchange by which you change the patient's free-association into an interpretation? There are all kinds of interpretations and all kinds of facts which have to be interpreted. You may care to think of some of these kinds for yourself. An example would be the man who looks at the sky and says, "I think it will be fine". We do not usually bother whether he is a qualified meteorologist or

not, but we do decide whether to take his word for it, as if he were an authority on the weather. The problems to which I am trying to draw your attention are as familiar to you as that, but the domain in which we operate is not familiar.

Freud foresaw correctly that the symbolism of dreams would be sure to change, because the unconscious knows how to defend itself by changing the symbolism as soon as it has been recognized. The analyst may not be as flexible as the unconscious. The language that he has to use is certainly not flexible, but has to be one which we are accustomed to use in everyday life. Mathematics are perhaps the closest approximation to what Croce called a 'universal linguistic', speaking of aesthetic, as any of us are likely to meet. We do not usually tell a highly qualified mathematician, "I don't know what you are talking about", as if it were his fault. A psychoanalyst, on the other hand, would be surprised if he did not detect that note of contemptuous hostility when he draws attention to what is unknown. As psychoanalysts we should be wrong to imagine that we are free from the same contemptuous hostility when we do not understand.

Freud said it would be unrealistic for a psychoanalyst to compile a dictionary showing what various psychoanalytic symbols meant, because he foresaw changes; we, his successors, are not so open-minded. It is un-psychoanalytic to adhere to some rigid system as a substitute for using our minds. The analyst must have a training, but it is not a memory training in learning the meaning of psychoanalytic symbols. Even in language itself a dictionary is not all that is needed; one has to understand the nature of language as well as the actual language in which one is attempting to speak. In analysis there is not time, as there is when reading a book, to consider what sort of transformation, interpretation, mechanism of exchange to use before we can give the analysand the interpretation. While the analyst is trying to understand, more free-associations occur and he has failed to hear them. That is why I say that 'understanding' is inappropriate during the analysis. The analyst needs a certain disciplined agility of mind in order to interpret or transform what the patient is saying into a currency which he himself can use.

Although money, like language and art, has turned out to be a valuable invention, it can be and has been debased. The skill to manipulate it can be acquired without the ardours of thinking the

problems through. As psychoanalysts we are inviting the 'yes I know' group, however large, powerful and wealthy, to suspend the operation of that valuable but dangerous frame of mind. Fear and hostility are aroused at the prospect of what might take its place. The mental 'black hole' is a case in point [see p. 100].

We know that we believe, to speak analogically, that only when a 'debased currency' has been discarded is there room for something better. We cannot guarantee that it will be better; not even analysed people, or experienced men and women, are better characters than they were when children – 'better' is a matter of opinion which is possible after the comparison can be made.

Q: The experience I have had in relation to your work has wakened me to the field of reality and truth. The reality or the truth and the experience itself fits into an area of infinite space. Your communication brings a need for order and reasoning, and in this there is the process of restriction and the loss of something more. You attempt a new form of becoming able to know – not of knowing, which the mind is already used to. That is a poison which creates the expectation of the habitual or normal. I think you are providing, fragmented and scattered, a new sense of knowing, or a new form of meaning in which that which is significant remains in the dark. Does this bear any relation to your experience?

Bion: Although we are accustomed to think of psychoanalysis as a revolutionary change, we hate revolutions and changes when they affect us personally. Consequently, there seems to be a constant warfare between the attraction of something new and one's wish to remain in a familiar field, or state of mind. If we keep in contact with the actual practice of psychoanalysis it is constantly a surprise to find that we are, in fact, still involved in a revolutionary experience. I am reminded – in astronomical terms – of being able to detect the continuing appearance of a colossal explosion which took place three or four, or a hundred light-years ago. The psychoanalytic experience is still exploding, and we can still experience moments when we are suddenly aware of being caught up in a mental turbulence. It may be worth re-considering the discussion of the 'black hole' [see p. 100 et seq.], considering it afresh in the light of your personal experience 'tomorrow'. Every time an analyst sees something freshly, everything that he has considered becomes worthy of re-consideration. This

'repetition' is an inevitable concomitant of growth; it must not be confused with 'repetition compulsion', although sometimes it may seem to be similar. I leave it to the reader to consult his own experience and the extent to which it throws light on the present and future, and not simply the past. Can he 'detect' turmoil? We are unlikely to welcome the capacity to do so. This continuing mental activity can be so hated or feared that the person who experiences it thinks that he is having what he calls a 'mental breakdown'. The practising analyst must get hardened to mental breakdowns and become reconciled to the feeling of *continuously* breaking down; that is the price which we have to pay for growth. We cannot fall back on the idea of being cured, because that is an old-fashioned and inappropriate term. We have to be reconciled to the feeling that we are on the verge of a breakdown, or some kind of mental disaster; we have to have a certain toughness to stand this continuing experience of mental growth. The alternative to it is to try to reconcile oneself to the fact that one is over and done with, that one has reached the final upheaval of mid-life, or old-age, and so forth. But then you have to pay the price of feeling that there is nothing more to come. So you can take your choice: mental stagnation and decay on the one hand, or perpetual upheaval on the other – like living in the middle of a mental breakdown, without being clear whether one is breaking up or breaking down.

Q: I would like to hear you speak about transformation in hallucinosis.

Bion: Hallucinosis is a word which one uses as a compact summary of an emotional experience. It has a somewhat pejorative meaning, but the thing itself has to be treated with more respect than to be deposited in a psychiatric dustbin. I would like to see the state of hallucinosis treated with the kind of respect which we expect to accord neurosis, dreams, nightmares and other mental phenomena; we can then hope to learn more about it. I would like to say to the questioner: don't bother what *I* think about it, but have a good look at it when you feel that you have a chance of examining a state of hallucinosis. If we can respect hallucinosis we may be regarding a future mathematician – not mere mental debris.

Q: You have said that one of the difficulties the analytic institute training committee has to face is a question of who to qualify as analysts. You suggest that this should be someone who could come

to feel that he is not invulnerable to a mental collapse. I would like to know what you think about the question of intuition to which you give a great deal of importance for the analytic job. I want to know if it is possible to see or recognize the qualities of intuition in someone who is to be qualified.

Bion: I find it difficult to believe in the intuition of anybody who is afraid of, say, hallucinations, or breakdowns, or any other frame of mind, because intuition is indivisible – either the person has intuition or he has not. He cannot say, "I will have just a little intuition, but I don't propose to have anything to do with people who are hallucinated". If it were possible for a candidate to talk in those terms I should say "All right; you can leave out psychoses and all that, but if you do you will very soon find yourself wanting to know nothing about terrifying dreams", and from that time on the individual concerned is firmly set on a course of rejection and retreat. I do not think I would be impressed by a candidate who thought that his troubles were all over when he was qualified; I would wonder what those troubles were that were all over. In the same way, our troubles are not all over when we have finished our childhood. Childhood, and even analysis, is only a sort of prelude to real life. Marriage is not the end of your troubles; there may be an end to playing games like 'fathers and mothers', but when you have finished playing your games then you *become* a father or a mother – that is the real thing. One thing you might learn in the course of your childhood games is that they are, after all, games. So, when you come to your real troubles it might be helpful if you could mobilize the kind of feeling you have when playing a fascinating game. It is not necessary to regard married life as a tragedy, the kind of thing which makes people say, when a friend gets married, "There goes a good man".

Q: Although Freud rejected philosophy as a rationalization which could obscure the truth, we know nowadays that our philosophies are various points of departure – mathematics, history, the power of reason, or irony, as in the case of Socrates. Do you consider that we are seeing the beginning of a philosophy of the soul which is also threatened with collapse?

Bion: With regard to Freud's idea of philosophy as a rationalization, I do not think that we can afford to kick away the ladder up which we climb; although the classical, philosophical views of Plato do begin

to prove inadequate, they nevertheless served their purpose. If one sums up Plato's writings about injustice as a belief that every cobbler should stick to his last, then all would be well if every individual stuck to the work for which he is best suited. It is not a bad idea, but it does become inadequate. By the time of Saint Augustine the classical philosophical approach had to be extended in the way in which he attempts to do in *The City of God.* That was partly an attempt to repudiate the responsibility of the Christians for the fall of Rome, suggesting that there was another kind of city of greater importance. Today we could say that there is a frame of mind which is more important than that which can be summed up as "every man sticking to his last". Analysis suggests that classical, philosophical disciplines and views are not enough; they have to be augmented by recognition of the unconscious and unconscious motives.

Philosophers are aware of 'rationalizations' though the term has not been in frequent use. They are concerned with correct thinking because they are aware of incorrect thinking – although they may not have devoted much time to the elucidation of the 'incorrect'. Usually, incorrect thinking has been relegated to grammarians and rhetoricians as if they were an inferior class, not worthy of the title of 'philosophers'. Incorrect thinking has thus been enabled to flourish undetected until it has now reached its present dominance and power. We may not now be able to arrest its triumphant progress. As one of the depressed classes, thinkers (whatever else they may call themselves) labour from a position of weakness; from my reading of history I doubt that this is anything new, although it may be novel to advocate awareness of discomfort.

5

Q: What is your opinion with regard to the teaching of psychoanalysis in universities or medical schools? If psychoanalysis is confined to the experience between two people, how can this experience be made use of in large groups?

Bion: The difficulty is to know what it is that the university, or the institution which is not psychoanalytic, expects from the analyst. The accounts that I have had in the past from people who have responded to the invitation to make some contribution to the university curriculum appear to be somewhat unhappy. The analyst often seems to find that something is expected of him which is based on a misunderstanding of psychoanalysis. This may be because we have made much more progress than we realize and are, therefore, familiar with a way of thinking and a way of teaching which is considerably separated from the ordinary conventional methods. My experiences of psychoanalytic training were, in fact, very depressing. Like the first railway coaches which were made to look as much like horse-drawn vehicles as possible, I found the whole apparatus of training was just a copy of the methods suitable for conventional training in conventional experience. But as I became more and more acquainted with psychoanalysis, the more utterly unsuitable this seemed. Some of it was due to the fact that we were all tired people, listening to people who were even more tired at the end of a day's hard work, who then fell back on doing what everybody else did. As I sat in small, overcrowded, uncomfortable rooms I thought that this was more suitable as a penitential exercise than anything connected with a cultural activity. And the more I became acquainted with psychoanalysis, the

more frightful this experience seemed to be. I do not feel optimistic about these requests which are made to our institutions, or about the effect it would have on our members. I would not discourage anybody from going to a university, or joining such a course, but on the other hand, I would not encourage them to believe that they are in for an enjoyable experience. It takes only a short time to discover that the students and other colleagues have a low opinion of psychoanalysis and the intelligence of the people who engage in it. This peculiar gap is very difficult to bridge.

The fact that psychoanalysis is fundamentally based upon a respect for the individual is liable to exacerbate the respect that we must also feel for the community of people. It is one reason why a study of the group may be a valuable adjunct to the psychoanalytic study of the individual, and vice versa. I think it is premature to pronounce an opinion on how these streams of experience are to be harmonized when groups and individuals meet. The problem is worth studying.

Q: I would like you to speak about your analytic experience with schizophrenic patients.

Bion: I once would have thought that I was having some experience of schizophrenic patients, but I am wondering how I would describe that experience now, and how I would regard the patients who I once thought were adequately described by the term 'schizophrenic'. I even used to take it for granted that the categories into which they had been placed were adequate. But as time went on I thought that these diagnoses were meaningless. I could not help being suspicious of a diagnosis which seemed to include a large proportion of all psychotic patients. Kraepelin [Emil Kraepelin, German psychiatrist, 1856–1926] himself seemed to feel that there was something wrong with the diagnosis. Of course, should the patient make any progress it can always be said that the patient was obviously wrongly diagnosed – however authoritative the diagnosis. It is possible, but I think there is something wrong with the assessment of the progress. If that were applied to physical medicine one would have to say that any case successfully medically treated cannot have been ill in the first instance. In fact, there is something wrong both with the diagnosis or its implications, and the whole experience of the analytic approach If I have not subjected the individual to analysis, I have no material on

which to form a judgement. If I have, they have all been patients who were aware of the relationship with myself. How they would or could formulate the experience of that awareness gradually unfolded with the passage of time. I have tried to describe it in occasional papers. Today I do not regard any diagnosis as an abridgement on which I could rely for illumination. I hope that my analytic approach would stimulate both the analysand and myself.

Q: What is your opinion of the case in which the patient cannot make any further progress due to an impasse in the analysis?

Bion: The analytic relationship between the analyst and the analysand is not unique. What would be the point of it if it were? The relationship between those two people is reminiscent of the relationship of any other two people. The impasse needs analysis both to enable the analysis to proceed and to familiarize the analysand with a problem which he is sure to meet in real life. Why do husband and wife sometimes seem to come to an impasse? If we have the chance of analysing one of such a pair we are sure to meet the impasse at some point; if not, what has it to do with real life if we never have a close-up view of something which is so common? Similarly, if frustration and anxiety are a part of real life one ought to come across them in analysis. It is the analyst's function to help the analysand to some experience of an impasse, frustration, or anxiety, and if possible to enable him to become familiar with dealing with it.

Q: Continuing the remarks about these impasses in analysis: when should analysis end?

Bion: It does not end; the relationship between a particular doctor and a particular analysand does. The ending is an event of no importance; everything comes to an end. The only reason it becomes important is because the individual has difficulty about termination. After all, we all die at some time. It is difficult to see why anyone attaches the slightest importance to it, except that one could say that dying is a dangerous thing, because most of us feel that if we died we should end up by being dead. That event assumes such importance that it is liable to obscure the short experience which intervenes between the time we are born and the time we die. We do not live for more than a few short years and it seems amazing that so much attention should be paid to such a trivial and unimportant affair as the finish.

People regard the termination of life as a sort of prize-giving; they are waiting, as it were, to receive their prize – or perhaps a very bad report. So, while time and energy are devoted to this unimportant event, life flows by.

Q: What are the similarities and differences between interpretations and constructions, principally in relation to your theory of transformations?

Bion: The view, expressed by Freud, which I found has a great deal of meaning for me is that many of these interpretations are almost meaningless, but these constructions are not. I remain unexcited by being told that I am omnipotent, or that I am helpless. I do, however, feel slightly more interested if somebody says that I think I am God; if it means nothing else, at least it means that somebody is being rude. To that extent it is an improvement on being told that one is omnipotent. But I would go further; I would like the individual concerned to tell me what sort of god I was behaving like. There is a large variety of gods which one's behaviour could resemble. If the individual, instead of being rude or hostile, would tell me which kind of god I resembled, I would find that construction much more meaningful and comprehensible. There is much to be said for a short story which I can understand and which, therefore, is a vehicle which communicates meaning. For example, if somebody said that I am like the god of Babel, that I am so jealous and envious that I would not like anyone to climb up a higher tower than the pedestal on which I was happening to sit myself, that I would like to make them so confused and on such bad terms with one another that they would not be able to construct a better and higher and more glorious tower – if I were given that sort of interpretation I would feel that I had a clearer idea (although I might not like it) of how I appeared to somebody else. That is why I am more in favour of the construction than some word that I could look up in the dictionary leaving me no better for the expenditure of time.

Q: What is the analyst to do if the patient suffers a psychotic episode and has to be hospitalized?

Bion: If the minimum conditions for analysis still exist I continue to analyse the patient. Putting the patient into hospital has little to do with the patient's personality; it has more to do with the public, or

the family, or the people who are feeling inconvenienced – perhaps seriously so – by the patient. If the patient is going about wanting to murder his fellows that is very inconvenient indeed. Extremes of this kind are easy to comprehend; it is more difficult when the person in question is a nuisance – like Solzhenitsyn. Should he be hospitalized in a psychiatric 'cancer ward', or just exiled? This matter of diagnosis is often a question of what degree of irritation or annoyance or inconvenience the person is creating. However, as analysts with a prejudice in favour of the individual, we would like to know what *kind* of nuisance the person was. Even if we narrow it down sufficiently to use some term like 'psychosis' we would like to know which particular variety of psychosis.

Q: Is it possible for religious feeling and psychoanalytic thought to co-exist in the same person?

Bion: Psychoanalysis is primarily a method of investigation, and we are, therefore, sure to come across some evidence of the views or beliefs of the individual. But I regard that as an irrelevance; in theory we are not supposed to impose our views on other people. I can see that there may be psychoanalytic views about religion, but they are departures from a method of investigation. Just as in any investigation we have certain preconceptions, it is impossible to ask a question without betraying your knowledge about that question. For example, any question regarding sex shows that the questioner knows something about sex, and at the same time shows that he does not know much about it. When it comes to an investigation of a religious belief the same thing is true of the analyst; it would be clear that he was showing his religious belief *and* religious ignorance.

Q: I would like to hear something of your experience of alcoholics and your ideas on the subject of alcoholism in general.

Bion: Alcohol, like any other form of food or drink, can be turned to good account or to something harmful. There is nothing particularly wrong with alcohol, but there may be something wrong with the individual who is taking it. There is a long history of the belief in the value of alcoholic drinks, wines, and a long history of the greed which affects the quantity taken. No one asserts that food and drink are harmful, but the consumer can take either food or drink in such quantity that the actual food or drink ceases to be adequately assessed

by the quantity and becomes a qualitative change. The harmless substance becomes toxic. It is one of these instances in which change in quantity leads to a change in quality. The same thing can be said about psychoanalysis; taken in moderation it is good for us. But what is moderation? In everyday life one likes to believe that the parents have an idea where to draw the line: not so the child. For a certain period in life there should be somebody who says, "I think you have had enough". It is awkward when there is no authority to make that statement, because the individual is no longer a child, and cannot justifiably be put in a mental hospital. Although 'alcohol' is not a crime a considerable number of families have been ruined by the excess of one member. Similarly, the predominance of one or other quality of an analysand may amount to an 'excess' to the ruin of that individual. That does not mean that the quality was a defect. Excess of brilliance of illumination, literal or metaphorical, can be as 'blinding' as obscurity. In short, to say that the person is addicted to a drug may save him from the need to submit to or seek investigation, or it may indicate the 'area' in which investigation is to be pursued. From the exercise of judgement there is no relief.

To return to the subject of the universities; would it be a good thing to introduce a psychoanalyst into a university, and would an analyst be in a position to say, "I think that your university is poisoning the youth of this nation"? I understand that Socrates got into some trouble in this matter; he was effectively dealt with on the grounds that he was corrupting the youth. Plato, in his *Apology*, argues very strongly against that view. However, it did not do Socrates much good. What is to be done about the poisonous food which may be destroying the future chances of the human race? Nobody has found a way of telling what kind of knowledge becomes toxic when one is talking about the mind or personality. It is a matter to which we should pay attention. It is something of a race against time.

CLINICAL SEMINARS

1975/1978

‘Clinical Seminars’ was first published in 1987 in *Clinical Seminars and Four Papers*, by Fleetwood Press, Abingdon. It was reprinted in 2000 as Part One in *Clinical Seminars and Other Works*, edited by Francesca Bion (London: Karnac Books).

Clinical Seminars

INTRODUCTION

In 1975 Wilfred Bion and I were invited by Professor Virginia Bicudo to spend the month of April in Brasilia. During that time Bion worked with individuals and groups, gave three lectures at the university, and took part in three panel discussions (entitled *Brasilia, A New Experience*) at the Buriti Palace to mark the fifteenth anniversary of the founding of the city. Panel members, representing the arts and sciences, dealt with aspects of the character of the city and the problems involved in forming and developing a new community. I have included his contributions to these discussions.

In April 1978 we spent two weeks in São Paulo – our third visit. Bion held fifty clinical seminars, daily consultations, and ten evening meetings (published in *Bion in New York and São Paulo*). Such a volume of work demonstrates his remarkable vigour and stamina at the age of eighty.

These clinical seminars, at which Bion preferred the number of analysts present not to exceed six, were all recorded. I am grateful to those responsible for having made possible this printed version.[1]

Owing to the variable quality of the recordings, I have been unable to piece together some of the clinical material, and after a lapse of so many years it has proved impossible to retrieve what has been lost. The necessity for translation (in both directions) significantly reduced the amount of ground that could be covered in each hour.

I have chosen to publish only those seminars that are sufficiently complete to form a coherent whole. The necessary editing in

[1][Francesca Bion was not present at the Clinical Seminars, in view of the confidential nature of the material discussed. They were attended only by clinicians. *Ed.*]

transferring the spoken word to the printed page has not in any way altered the content of Bion's contributions or his style of expression. I have adopted the same methods as those I used in the past with his approval.

He had no prior view of the material presented; the patients under discussion were being 'seen' by him for the first time. His responses were, therefore, spontaneous and give a clear indication of how he worked as one of the psychoanalytic pair.

BRASILIA

1975

1

Presenter: I would like to discuss a session I had today with a thirty-year-old woman. She came into the consulting room and sat down; she never lies on the couch. She smiled and said, "Today I won't be able to stay sitting here." I asked her what that meant; she said she was very agitated. I asked her what she considered as being very agitated. She smiled and said, "My head is dizzy." She said her thoughts were running away, running over one another. I suggested that when she felt like that she also felt that she was losing control of her body. She smiled and said, "Perhaps; it looks as if that were true." When I continued, suggesting that when her mind was running away like that, her body had to follow her mind's movements, she interrupted me, saying, "Now, don't you try to make me stand still."

Bion: Why should this patient think that the analyst would *do* anything? You cannot stop her coming or send her away; she is a grown woman and presumably therefore free to come and see you if she wants to; if she doesn't want to, she is free to go away. Why does she say that you would try to stop her doing something? I am not really asking for an answer to that question – although I would be very glad to hear any answer that you have – but simply giving an example of what my reaction is to this story.

P: I was interested to know why she had said, "Don't try to keep me still". She said she didn't know the answer to the question, so I suggested that she was preoccupied by my being quiet, still. She said that she did not regard me as being still, but as dominating my movements, my mind controlling my body.

B: As you have been seeing this patient for some time, you both know a certain amount about one another. From the point of view of the group here, I wonder what any of us thinks so far. Do you get a

feeling that you want to know more? Or do you feel that you would not want to see this patient again? In fact, I would like to hear what she had to say without my asking questions – were it not for the fact that that is such an extraordinary way to behave. We tend to forget that we may be much more used to analysis than the patient is. It would be quite natural to me to sit there silently and hear what the patient has to say, but the patient might not be able to stand that. A patient coming to me for the first time might be so frightened at such peculiar behaviour that he would get up and walk straight out. So as usual we come back to this point: in *theory* we can read what we like in all these great books on analysis; in *practice* we have to have a feeling about what the patient can stand. One's behaviour has to be a compromise; one has to have some concern and make allowances for the patient to whom this is such a frightening experience. I think this is an argument in favour of our behaving in a fairly conventional manner to make it easier for patients, who are under a strain anyway, to say whatever they want to say.

I would like to make a guess here as to what I would say to this patient – not in the first session but later on. "We have here these chairs, this couch, because you might want to use any of them; you might want to sit in that chair, or you might want to lie on that couch in case you feel that you couldn't bear sitting there – as you say today. That is why this couch was here when you first came. I wonder what has made you discover this today. Why is it that only today you have found that you may not be able to sit in that chair; that you may have to lie down or go away?" All that would be much more appropriate if she had discovered it at the first session. But she was too afraid to discover it.

P: In earlier sessions this question of sitting in the chair and lying on the couch had already arisen. But I am considering the idea of this being the first session.

B: Every session is really a first session. Today isn't yesterday; what the patient is saying today is because it is another day. Of course it is true that it is also because the patient happens to be that particular person.

P: You mentioned making a compromise when the patient first comes for analysis. If every session is a first session, why would there be a reason for changing attitudes afterwards?

B: Because time is passing and the patient is changing. If it were possible for the patient to make no change at all, there would still be a change because the world is going on; it doesn't stop because we refuse to grow up. It is made a bit easier if the analytic pair remains recognizably the same; it gives a certain familiarity. Similarly, the mother needs to be recognizably the same person every time she comes to the baby; the baby needs to feel it is the same mother. In the analytic situation it is more difficult because the patient is not a baby and the analyst is not the mother. So once more the analyst makes allowances for the patient by being recognizably the same person. But that doesn't mean that one has agreed that the situation should remain static, frozen. Indeed in this respect one is really putting pressure on the patient to grow up, not to remain a baby or a patient or a neurotic or a psychotic for ever. The analyst expects something from the patient besides just punctuality, fees and so on; he expects some improvement.

P: Your suggestion of what to say to the patient seemed much simpler than what is usually said by an analyst.

B: In a way psychoanalysis is extremely simple, but like every simple thing, for some reason it is awfully difficult to carry out. Similarly, while we always talk – and I think rightly – about sexual problems, it appears that physiologically and anatomically nothing could be easier than having a baby. The objects concerned only have to wait until they are fourteen, fifteen, maybe much earlier, and then they can have a baby. What could be simpler? But the trouble is that we, rightly or wrongly, believe that there is such a thing as a character or personality – the whole of psychoanalysis is based on that somewhat all-pervading theory. So this very simple activity is complicated *if* the person concerned knows that to have a baby there has to be long preparation beforehand – thirteen or fourteen years of it anyway – and a long time afterwards. Birth is nothing at all – it is a sort of milestone – but there is a long period of development both before and after it. When it comes to the mind or personality, we still don't know how long it takes to create that.

As the analyst, one hopes to go on improving – as well as the patient. That is why I think it is a good thing to leave oneself a chance of learning something and not to allow the patient, or anyone else, to insist that one is some sort of god who knows all the answers. If

I knew all the answers I would have nothing to learn, no chance of learning anything. So while the mother or the father must be able to bring up the child even after birth, it is also necessary to leave room for the person to be able to behave like an ordinary human being. It is hopeless if one feels condemned to be, as it were, the great father, or great mother, or great psychoanalyst, or great anything. What one wants is to have room to live as a human being who makes mistakes.

To come back to this patient: if I make allowances and say, "All right, sit in the chair if you want to", or "Lie on the couch if you want to", will the patient make good use of that? Or will she feel that if I have allowed that much freedom, then she will take a bit more? For example, the patient can then say, "Well, all right; if I can lie down here, I'm going to lie down and go to sleep. I'm going to have a never-ending analysis. I'm going to spend the rest of my life coming to you for analysis. I'll camp out in your house".

P: I felt that the patient was trying to feel free to talk with me, but that the liberty to talk with me was at variance with the terms she wanted to impose. I asked her what she would think if I behaved like she did – my mind not controlling my body. She said it would be excellent.

B: I don't think I would want to ask that question because I would be afraid she would give me an answer which might not be the correct one.

P: When she said it would be excellent, I suggested that she was telling me that she saw a chance of us both being connected, married. She said she didn't like the word, 'married'. She remembered then – although she insisted on not using the word, 'married' – that she had had a dream that night in which she saw our faces and mouths close together. The sensation was a very exciting one although there was no orgasm involved.

B: She can say, "I'd like that", but this depends on the belief that you wouldn't do anything; she is sure – or thinks she is sure – that you would not marry her. In other words, she wouldn't mind saying how much she would like to have sexual intercourse, or how much she would like to be all alone with you, or her father, or her mother, provided she didn't have to do what fathers and mothers do. So far it's not so bad; she may have been very close to you, but it was only a dream so it doesn't matter. But we, as analysts, think dreams *do* matter, and so would this patient at some time in her life before she

made a distinction between a fact when wide awake, and a fact when fast asleep.

I would begin to be a bit suspicious about this patient; I would wonder whether she really knows the difference between a dream and waking life, or whether she knows the difference between courtship – a love affair – and a psychoanalysis. However, the immediate point is, what shall we say to the patient? It is time, as it were, that we gave her an interpretation. There are millions of interpretations, but there is only one experience, and that is the experience which the analyst here had with this patient – while none of us had it. We can discuss the matter, but that is not analysis; that is *about* analysis. The feeling the analyst has that something is taking place, can only be known if the patient comes to him and gives him a chance to experience it.

2

Presenter: The patient is a woman, about fifty years old. In the session I am presenting she arrived, kept silent, and then in a demonstrative way yawned and showed that she was sleepy. Then she said, "Why did I come here if I am sleepy? I should stay at home to sleep. I don't come here to sleep". Between each phrase she was silent. I said nothing. After a longer silence she asked, "Why do I come here?" I asked her, "Yes, why *do* you come? What does coming here mean to you?" She answered, "This means that; this is that". I pointed out to her that this didn't tell me anything. She continued, "Well, I come here to get to know myself better. I think that with your help perhaps things will be clearer to me". But she said this in a very unrealistic way.

Bion: One could say that if that is the answer, then what is the trouble? She is hardly likely to come to ask a question to which she thinks she knows the answer. If you ask her, "Why did you come here?", then she can say that is what she is asking you. So I think I should simply leave it and say to her, "You have posed the question; perhaps later on you will be able to say what the answer is!", or simply say, "You have posed the question". I would rather leave her the chance of saying what the answer is when she has found it. It is as well to bear in mind also that there are two people in the room and that this question can apply to one or the other, or to both of them.

P: Suddenly she interrupted herself as if remembering something I had told her before. She lay down on the couch and turned her head towards me saying, "Didn't I say anything? Well, you said it doesn't mean anything". She stared at me and then said, "You said I didn't say anything – perhaps I didn't say anything". I said, "You

look at me as if I know the right answer and that you are supposed to guess it but you can't". Then she said, "You could help me, but you keep saying that I have to do everything by myself here". I said she was attributing me with the ability to help her.

B: I would have thought that you were working too much. My own feeling about this – as far as I can tell, not having been there – is that I would prefer to remain silent and leave the patient to tell me the answer to this question. If I wanted to say anything at all I would leave it in abeyance. She has asked a question and nobody has answered. The only thing I have heard is a silence; there is apparently no answer to it. I wonder in what way she knows that she has to do all the work. Who has told her this, and what is she hearing in this silence? I don't object to the silence because there are in fact some forms of communication in which people remain silent. There are 'rests' in music – the instruments don't play. So I think I would still leave it at that, or I might – depending on how familiar I think she is with this situation – draw her attention to the fact that she must have some way of hearing what has been said when nothing has been said. Either that, or it is not true. As far as I am concerned I would expect somebody to tell me if I have to do all the work. Otherwise you may get into a situation where you are supposed to help her without any assistance yourself. You haven't gone to see her; she has come to see you.

P: She says she doesn't know why she comes.

B: My reply to that would be, "I think that is very unlikely – if you don't know, certainly nobody else does". It sounds much more likely to be true that she doesn't know why you, the analyst, have come. But she may be puzzled as to why both these people have come; there are two people in this room alone, but she doesn't know why they are there, or what they are there for.

In this situation her explanation of finding out about herself is more or less plausible; it is a reasonable explanation; it may even be a psychoanalytic explanation. It sounds to me as if she has come into this room where there are two people and has started asking questions about what they are doing. It would be much easier if one could say that there is a little girl watching what these two people are up to.

Let's leave the matter and let her go on talking if she wants to, so that we can then listen to what she is saying to that man who is in the

room with her. So far, apparently, neither the man nor the woman has said anything except something which sounds like a very unconvincing psychoanalytic interpretation. In short, the mystery is unsolved.

P: I brought this case because I am very uneasy about it.

B: Yes, and so is she. She doesn't know why those two people are there. You have to attach great importance to what she does say – all these 'whys'. The patient who asks a question and sees to it that you can't give an answer because there is already an answer there, leaves no chance either for you to be curious, or for her to be curious. She can ask a question and she can get an answer which tells her nothing. The same thing applies to you; you are asked the question, but you are told nothing. If you try to give an interpretation, the patient retreats further on the basis that, "If you are so very clever, you tell me". You shouldn't give in to that, but make it clear that if she wants answers to these questions she will have to keep you properly informed. Analysis isn't a game – not as far as the analyst is concerned – in which you are asked to give an answer with nothing to go on. You give an answer and she gives you another question; in the end you find yourself trying to give help with no way whatever of giving it. Alternatively, if you don't give her any interpretation, if you maintain silence, she can say, "There you are – I am supposed to come here and do all the work". That is really a sort of blackmail. She will prove that the analyst is wrong anyway; either he is so ignorant that he doesn't give any help, or else so clever that he can do the job without any assistance.

Member: In talking about impressions you have, you suggest what the analyst might have said to the patient. You also mention interpretations that occur to you but that you would not say to the patient. Listening to these two kinds of interpretations I feel that any of them could be given to the patient.

B: In the *practice* of analysis the analyst has to make up his own mind what the situation is; there is nobody to tell him this – only his senses, what he hears and sees for himself in the room. It is the fallacy of training that one is told the interpretations to give. The only place where you have a chance of knowing what the interpretation is, is in your own consulting room. Nobody can tell you more about it than you know yourself. With different people, different situations arise; even with the same person – today isn't the same as yesterday. It is a dynamic situation; analysis is not static. Analytic theories are quite

useful for about three sessions – you know nothing about the patient and therefore have to fall back on theory. After that the answers are on the couch or in the chair, and in what you can see and hear for yourself.

P: I told her that when she says I have the power to help but don't want to, and that I say she must do everything for herself, she means that she is completely dependent on me, addicted to me. But as she knows that I have this power, she can go to sleep till I make up my mind to help her. The only thing she said was, "I am not addicted".

B: In that case she must know what she *is.* Why doesn't she tell you what she *is* if she knows that she is not something? Psychoanalysis is not a way of telling people things we don't know; it is much more a question of finding out something. The analyst hopes that he will know a little bit more about the patient each time they meet. We are not trying to teach patients that we know all the answers, but that if *they* do the work they may find the answer. Nobody is going to do the work for them because no one can.

P: She came back to the point about what she gets from the analysis – knowledge about herself and so on. She said, "How difficult it must be for you to stick it with me". She told me that although it is terribly difficult here with me, she knows that she is improving. Then she said something absolutely unintelligible as if she was eating the words. I told her I didn't understand what she said. She replied, "I mean the confusion in my mind". I told her that even when she wanted to get closer to me it was very difficult for her because as soon as she started to say that she was improving, she felt unable to talk freely and had to cause confusion.

B: If she was being fed, she could fairly soon discover that the food had something to do with what came out of the other end of her body. But you are not feeding her, so one has to think up something else. I could say, "You are feeling that you take in my good analysis and turn it into a lot of confused stuff, and then you have to have some more". If we were talking about the alimentary canal, we know that it takes a long time before a child connects what it eats with what it evacuates. By the time it is old enough to know the answer, it has forgotten the problem, it has forgotten the question. All this is much more difficult if you are talking about the mind – which is what we purport to do. Patients can feel as if they get good, clear analysis, but that it is turned into a lot of rubbish.

What is one to say to the patient? This is where *you* come into it; you are there and you know by this time something about the language that this patient understands. It is not simply a question of what *you* understand, but whether this patient could understand an interpretation that you could give. To take a ridiculous example, you can't launch out into a great explanation of the biology of the alimentary canal to a baby. It may be true, it may be the correct interpretation, but it is a nonsensical waste of time.

3

Presenter: The patient is a twenty-four-year-old man, a hospital physician. He arrived ten minutes late for the session. He started by saying, "I was downstairs. I hesitated to come up to the consulting room. I went to buy some cigarettes. I came to the consulting room but I stopped. I couldn't stay here. I took the elevator, not feeling well I thought it would be too difficult for me to come to the session. I thought that if I stayed here I would die. I almost went away. I really thought it was going to be too hard for me". He kept on talking but changed the subject. "As I told you on Thursday (the previous session – this session was on Saturday) I was afraid of being on duty on Friday – it was a twelve-hour job. When I finally went on duty it was too hard for me". This was the first duty he had been on for four months – it was impossible for him owing to his anxiety.

Bion: Was he physically ill?

P: He thought so but in fact he was suffering an anxiety crisis. He said that while he was talking with the other doctors he had the feeling that he was going to be ill.

M: Would it not be interesting to interrupt the patient at this point? I feel there is too much material.

B: Yes, you often get a patient who, in contrast to saying nothing at all, floods you with information. I gather that this is happening here. Ordinarily one expects there to be some kind of structure to which the total communication conforms. But if the patient is always changing the subject he isn't really conversing; he is flooding you with free associations, not assisting you, not keeping you informed so much as keeping you unable to give an interpretation. But I don't think I would be inclined to stop him until I got a clearer idea of what

he was up to. I suspect – I don't know of course; it's just a suspicion working in my mind – that this patient is one of those people who take up medicine because they are so frightened of some catastrophe or disaster. He can then converse with other doctors and thereby hear about all the diseases there are. Then he won't die, or disasters won't happen, because he is the doctor, not the patient.

M: Is this suspicion of yours one of those things the analyst should keep to himself, or could he tell the patient?

B: I think I would keep it to myself because one does not want to flood him with interpretations. He is already being greedy, wanting more and more, but instead of its helping him he gets flooded with it, he gets more medicine than he needs. A common manifestation of this sort of thing happens when medical students go to the dissecting room to learn anatomy. They break down; they can't go on with it because it causes such an upheaval in all their views and attitudes if they dissect the human body.

P: I have the feeling that the patient didn't change the subject – he only apparently changed it.

B: This feeling of yours is where the interpretation comes from. Otherwise, if you interpret all these various changes of subject, you miss the point, you miss the subject which hasn't changed. When you begin to feel that all these different free associations are not really different ones, because they have the same pattern, then it becomes important to wait until you know what that pattern is.

P: In a seminar with a training analyst, the analyst told me that every good interpretation should contain three elements: a description of the behaviour of the patient; the function of the behaviour; and the theory which is behind that behaviour.

B: In a sense these theories, such as this one you mention, have a use for the particular person who mentions them. Some of them will also mean something to you. While you are trying to learn, all these things are very confusing. This is why I think you can go on too long with training and seminars. It is only *after* you have qualified that you have a chance of becoming an analyst. The analyst you become is you and you alone; you have to respect the uniqueness of your own personality – that is what you use, not all these interpretations. If you can feel, like your feeling just now, that the subject hadn't changed, *that* is important. Then after a time you may have a chance during

that session, or next week, or next year for all I know, of finding out what this pattern is.

Take the session as far as it has gone: some idea could come to you and you could feel, "*Now* I can give the interpretation". But by the time the interpretation is ready to be given, the problem is solved. Every interpretation means that a change takes place – if it is a correct interpretation. The puzzling situation which has been made clear by the interpretation at once disappears; it is once again an entirely new situation in which there are new problems.

It may take a long time to deduce what the unchanging element is. In physical medicine we can find out all kinds of things about the patient – temperature, pulse, blood pressure and so on – and then add them all together. We may have to say, "I don't know what this is", or we may have to tell the relatives, "I think it may turn out to be an ordinary cold, but we'll watch him; keep him in bed and I'll come and see him again". A good doctor has to be able to dare to say to the anxious relatives who ask, "Doctor, what's the matter?", "I don't know yet – I'd like to know some more", or, "I don't know yet, but I think it may be turning into –" whatever the complaint is. In analysis the analyst has to be satisfied, otherwise he is under constant pressure to give an interpretation. With this patient you can feel that he wants, or ought, to get back to work, and that it is a serious business that he is absent. But the analyst has to be ruthless; he has to resist the pressure because his business is not whether somebody gets back to work or not, but that somebody be given the correct analysis. You are *always* under pressure. While you try to listen to the patient, he keeps on trying to shove you – "But doctor, I've got to go back to work", "I've got to do this", or, "I've got to do the other". All that has something to do with his life, but nothing to do with the analysis. If a surgeon is operating he cannot tolerate a great noise in the theatre; he cannot have people talking; there has to be a discipline so that he can concentrate on the particular job.

In this case you have to try to get the conditions in which you can give an interpretation. The patient will push you, give you so much material that you feel, "If I go on listening to this I shall never know what interpretation to give because there are so many associations". You have to try to resist that, to insist to yourself that you are going to go on listening to what he has to say until you are convinced that

you want to say something. Otherwise you can find yourself in the horrible situation of spending your life giving what you think is an interpretation that somebody else would give, instead of giving the interpretation *you* want to give. I don't think you can ever do good analysis if you are not satisfied with what you say.

While the analysis is going on you may remember something that someone has said – like the statement of the training analyst. It is like remembering something that you saw in a ward while you were a medical student. There is a lot to be said for hearing the way different people do analysis, but it must never make you lose sight of the fact that the only thing that matters is the way that *you* do it.

Let us go on with this case now. Perhaps we shall get some idea of this unchanging subject you have mentioned.

P: The patient had the impression that if he remained on duty he was going to feel ill. He was not feeling ill – he had the impression that this was going to happen.

B: In other words, he wasn't going to get cured – he would get these illnesses. It sounds possible that he has never really considered that he has to be very tough indeed to be a doctor at all. In this profession you are always dealing with people at their worst; they are frightened; they are anxious. It is no good taking up that occupation if he is going to end up by being anxious, depressed and frightened too.

P: So he left the room to lie down. At this moment he was called to the emergency ward. He went; he worked perfectly. He thought it very curious that he could work well without any difficulty.

B: There is a saying, "Every fat man has a thin man inside trying to get out". Could one say, "Every hypochondriac has a doctor trying to get free"? Or, "Every neurotic has an analyst trying to get free"? The answer is, of course, no. But to the surprise of this patient he discovers that there is a doctor trying to get free. He goes off to this emergency, and instead of having a heart attack or whatever, he finds that he can be a doctor. Using this not only for this incident but for many others, you can begin to feel that the patient may after all be a doctor or a potential analyst if, when it comes to a crisis, the doctor emerges. But why in a crisis? If it is really true that he may after all be a doctor, not just by title but the thing itself, why hasn't he discovered that till now? Why is it that he *had* to be neurotic or hypochondriac, or go to an analyst before finding out this point? Of course, we believe,

as analysts – rightly or wrongly – that analysis is helpful. But that belief is liable to hide from us the extraordinary nature, the mystery of psychoanalysis. Such a lot of analysts seem to be bored with their subject; they have lost the capacity for wonder.

P: Later on in the same session he asked himself this question and said, "If I had known that analysis could do this for me I wouldn't have waited for a crisis before coming".

B: One of the peculiarities of progress is that it always makes you feel depressed or regretful that you didn't discover it sooner.

P: He also talked about what an effort analysis was for him.

B: What he is not noticing is that he is actually expressing appreciation of the analysis. That might seem to be a very slight point, and as a matter of fact it is, but it is like the tip of the iceberg showing when most of it is out of sight. The patient does not notice that he is capable of putting up with his jealousy, envy, rivalry, and is then able to express appreciation or gratitude to the analyst. In all this mass of material which almost suggests that he has no faith in analysis and doesn't expect it to do any good, he is in fact saying that in his opinion analysis has done some good – or rather the analyst has done some good. That point frequently escapes attention partly because of this belief that analysts are concerned with finding fault – crime detection as it were. But we aren't; we are trying to find the patient, whoever or whatever the patient is. It is important, if you get the chance, to draw his attention to these expressions of admiration or affection or sympathy, because they are felt – particularly by a patient like this – to be such feeble things that they are not worth mentioning. He is dominated, I think, by the need to make reparation, to cure people. Behind that lies his dread of being destructive, or of being a person who is much more likely to make people ill than to cure them. It is very difficult to be condemned to be a doctor who cures people; it is a different thing to *want* to cure people. You are an analyst, or a father or a mother, because you believe you are capable of the affection or understanding which is so necessary but which is felt to be so unimportant. On a larger scale, it is felt to be much more marvellous to be a Hitler than simply someone who is concerned with the welfare of his fellow men. It is liable to be lost sight of that what we, as doctors and psychoanalysts, are concerned with is helping human beings, not making them miserable or upsetting them. We may have

to upset them in the course of the analysis, but that is not what we are trying to do. With this patient it may be very important to show him, when the time comes, that there exists some capacity for affection, sympathy, understanding – not just diagnoses and surgery, not just analytic jargon, but interest in the person. You can't make doctors or analysts – they have to be born.

4

Presenter: The patient came on time, looked very anxious, lay down on the couch, and was silent for a long time. Then she started to talk, saying that she couldn't come last Friday; she was cut off by the rain when she was leaving her job, so she couldn't take the car or get a telephone message to me. She was silent for a short while and then said, "Today I notice that I am afraid of you". She said she became aware of this fear when she heard there was a very famous psychoanalyst in Brasilia. She wondered if, being a psychologist, she could attend some meetings. People came to ask her how they should go about getting a place at the talks this analyst was giving. She didn't know the answer so she thought she would ask me about it. She said she was carrying on an inner dialogue with the following argument; "If I ask her, I know she won't give me the answer; if I don't ask her, I shan't know where the meetings are going to take place". So she decided to speak out and to explain the situation to me. I pointed out that the conversation with herself was a way of avoiding speaking directly to me.

Bion: Why did she say she knew she wouldn't get an answer?

P: Later on I raised this question. Her answer was that this arose from the kind of relationship she had with me.

B: How often does she come?

P: Four times a week. I have the impression that sometimes she feels in contact with me, and I myself feel in contact with her, but only occasionally. She has been in analysis for over a year. She has a baby girl, eighteen months old. A month ago she got a job as a psychologist, but not in the clinical field. Since she started working full time, her sessions are at the end of the day after she has finished work. Before this she never missed sessions or forgot to

pay the account or came late; now she arrives late and sometimes misses one session a week.

B: What about this point that when she does come you feel that she puts distance between you and herself? How does she do that?

P: I get this impression when she starts explaining why she is late, as if she were giving an explanation to a teacher or a mother.

B: Were you able to make that clear to her?

P: I have tried. Her attitude was one of, "Well, I know I am going to make excuses", and so whenever she arrives late she says, "I know I am going to begin to make excuses". I feel that she conveys something of an inner dialogue with herself, but that she never expresses fully what she wants to say to me.

B: There must be some reason why, knowing that she won't be able to make a contact with you, she bothers to come. Perhaps she thinks that famous analysts are people who are too famous to get near.

P: She uses the informal 'you' when speaking to me. She said, "I am going to put a question to you. I know you won't answer it, but I need to have an answer". I said, "You speak with yourself before speaking with me, and yet when you speak to me you don't actually do so because you already know the answer I am going to give". I got the impression that this both annoyed and saddened her. I told her that she seemed to be under constraint, not at ease. From past experience I have observed that whenever I mention something that I notice in her behaviour, she seems to wake up, to become livelier. She seems to be closer to me because of the vividness of her expression, happy when I make such an observation. And yet I do not feel I ever get near to her, even though she may express this kind of happiness.

B: What kind of happiness do you think it is?

P: I feel that when she suffers during the session, she uses distance to alleviate, expiate her feelings of guilt. When I point out that she is suffering she says, "No, not me, I'm not suffering".

B: It seems to me that she feels guilty and frightened because she is having an experience which doesn't accord with the psychoanalytic rules – as she knows them. I think that the 'famous analyst' is a person she doesn't feel able to talk to, and that famous analysts are not people who talk to *her* either. How does she know that the 'famous analyst' wouldn't have anything to do with her?

P: She usually feels that she is being criticized: she could have done better, she could have done more –

B: But I think something has happened to make her discover that she is near a 'famous analyst', and that therefore she must not talk to famous analysts or even know where they are. I suspect that she is feeling that a 'famous analyst' is disguised in the person to whom she comes for analysis. Leaving aside for the moment what one would say to this patient, let us discuss why it is that the 'famous analyst' is too famous to be spoken to.

P: Perhaps this is related to the fact that she has a sister who is very successful in her profession of clinical psychologist, whereas the patient only managed after a year to get a job. So even though she is a psychologist she has to keep to her schedules and be bound by the requirements of a job. Whenever she wants to mention something of importance to me, she puts her sister first and says, "My sister thinks . . .", "My sister mentioned . . .".

B: I suspect very strongly that she is discovering that her baby is a person. Something has happened which makes her think that the baby is something to be afraid of: if it were older, perhaps it might be much cleverer than she is; it would know if she deserted it and came to see you. She is afraid of this object which is felt to be a dangerous personality who knows a great deal more about infantile psychology than she does. She feels that *if* she could be as clever as her baby, *if* she could go back to that state herself, then she could know a very great deal about people. We give all kinds of interpretations like, "You felt this", or, "You felt the other", including those which are appropriate to something like being at the breast. But I think the baby knows a lot more about being at the breast than just ordinary psychologists and psychoanalysts.

Trying to put that into more 'reasonable' language, I suspect that this girl is very surprised at what she has produced, and is filled with admiration of that baby. Your interpretations may remind her of something she has forgotten from childhood or even infancy – the baby certainly will. The baby isn't her analyst, but the emotional situation between her and her baby is nevertheless one which stirs up feelings more powerfully than any analytic relationship does. She has been having verbal intercourse with you for some time; therefore there is always the chance that she might be pregnant. So in a way

she is really talking about feelings which she apparently did not work through before the baby was born, that is the fear of pregnancy, what the mother has inside her – even though she is now the mother. It is as if she has learnt all about psychology, but is afraid that psychoanalysis is either just 'the same old thing', or that it is something different. Then she will be rebelling against the psychologist – she being both the psychologist and the rebelling person. I think she fears knowing, not just hearing, that you have a relationship with a 'famous analyst' – whatever that is. So in this respect, if she comes to you she is very close indeed to a sexual parent – husband or wife. The same thing applies the other way round: if you are a good psychologist or psychoanalyst, you will know that she is pregnant, or you will know that she is going to give rise to a baby. We know of no symptoms in the mind like those of pregnancy, but this patient as a child could have known when her mother was pregnant even before the mother was aware of it. So there is anxiety about this 'famous analyst' who is sometimes her analyst, sometimes herself, sometimes her baby, and sometimes something which will emerge.

This brings us back to her statement that she is afraid of you; you have been hostile and envious either because she has this 'famous analyst', or because she is able to realize that her baby has a character and a personality. Nothing is likely to produce so much mental growth as being pregnant and having babies.

M: What about the man?

B: The man, instead of being the enviable, superior person who has a penis, is the envious, unlucky person who can't have babies. So whether you, the analyst, are a man or whether you are a woman, it is dangerous for this patient to have anything to do with you, or to come near you, because she doesn't know what you will do to her baby. If she behaves as if she has a famous baby, as if she loves and admires the baby, then sooner or later this will show in the analysis. So far it has been safe: so far she has not got near to her analyst; she has only spoken to her analyst as if there is a long 'telephone' line between the two of them. But she can feel a conflict between treating the baby as if it were a doll or a chunk of psychoanalytic jargon, and treating the baby as if it were a person. In a sense, one could say that a mother is being born; so there is some fear of allowing herself to say or show how pleased and how proud she is of her baby, because she doesn't know how jealous or envious her 'father' analyst or her 'mother'

analyst will be of this situation, or how angry the baby will be if it is left while she goes off and sees the father or the mother analyst.

I have talked a lot about that, but we haven't touched the real problem: what is to be said to this patient? You can't say what I have been saying to you – the patient would either go to sleep or walk out before you had finished talking. You have to consider which interpretation feels like the one you would like to give. The very close relationship between the mother and the infant is where you have a chance to find out something about yourself and something about the baby; that is a very superior sort of analysis. Psychoanalysis is simply 'playing at' knowing about mothers and fathers and babies – not the thing itself. What is at stake here is whether this girl would dare to allow herself to use her intuition and to be a real person talking to this child, and whether she will allow the real child to be a real child, and not get angry or frightened when she finds that the real child knows a great deal – or seems to. In other words, mothers and daughters and female babies are all things which are felt to be likely to cause a great deal of jealousy or envy.

I would hope to bring up to the surface this thing which is making it difficult for the patient to come to her analysis. It doesn't do the baby any good if the mother remains stuck with it. If you ever deal with a patient who has succeeded in preventing the father or mother from doing what they wished – being so disturbed or crying so much that the mother couldn't leave it – then later on in life that person will be unable to leave others.

5

Presenter: The patient is a thirty-five-year-old woman who has been in analysis for seven years and is in her second year with me. We agreed at the start on two sessions a week because it would be impossible for her otherwise. In the second year this was increased to three sessions a week. Last year I considered ending work with her, but I changed my mind. This year I have had the impression that we are beginning to talk to each other.

Bion: What made you feel that it was hardly worth your while to go on?

P: I felt that there was some kind of obstacle preventing us from communicating so that we could not talk effectively to each other.

B: What is this impression which grows up? I ask because it can happen with any patient; the analyst feels that it is too unrewarding a relationship to continue. The sense of an obstacle can crop up in anything, but sometimes it presents a challenge, a stimulation which makes one want to go on. I remember, when I was a student, having a patient who seemed to be so boring that it was difficult to keep awake. And then I began to feel that it was so boring that it made me wonder how he did it. So you may begin to be fascinated by the obstacle, and then it is possible to go on. But when you feel that it is so unrewarding that it is not worth continuing, that is a matter to which we need to pay attention.

M: Do you agree that there are some patients who are unanalysable?

B: I think that is true. It is sometimes forgotten that analysis is in its infancy, and to assume that it can cope with all kinds of patients may be quite fallacious. It may not be the fault of the analyst or of the patient, but simply that we just don't know enough. In physical

medicine tuberculosis was not so long ago regarded as a fatal illness. Today many tubercle experts are without a practice; the specialists have become redundant because of the advance in medicine. There may be things which will be treatable analytically fifty or a hundred years hence, but that doesn't alter the fact that they may not be treatable now. One could ask about this case: what led you to feel that it was time to terminate? And conversely, what led you to feel disposed to go on?

P: I was never sure if the difficulty of establishing contact lay with me or with the patient.

B: That is always worth considering. But here again I think there is a fallacious argument because analysts think that they can use a counter-transference. That is an inaccurate way of thinking. You can use a *feeling* you have, but counter-transference you cannot use. By definition I cannot do anything about my counter-transference; there is nothing to be done with it except to go to an analyst and get analysed. But most of us have to put up with the fact that there is no analyst to whom we can go.

One can feel one is bored with a patient, or the work is unrewarding, or the relationship doesn't progress It may be both the fault of the patient *and* the fault of the analyst – who is to blame doesn't really matter. There is nothing that can be done about the analyst's fault except to make allowances for it. The only question that remains is, can anything be done with the part of it that the analysand contributes? In a way the progress of analysis depends on just that – it seems to be possible to help one's analysand to be a better analyst than one is oneself.

P: At the same time that I was aware of these feelings I also noticed that the patient never missed a session. But I had the impression that the language I used did not touch her and that she could never understand it.

B: Who pays the patient's fees?

P: She herself.

B: Does she pay the right amount regularly?

P: Yes – she is never late with her payments.

B: This is something which is very characteristic: the absolute regularity of attendance and of payment. You can tell the time by her coming; she can tell the time by the analyst's coming. Financially it always looks as if one knows exactly what one is being paid – you can

count the dollars or cruzeiros or whatever the currency is. So there are two things that *appear* to be comprehensible. I have known this regularity of payment and keeping of sessions with a patient who had been certified and yet was able to keep the appointments – whether wet or fine, a strike in progress, it made no difference. How can such an ill person do something that seems to ignore all kinds of facts, and go on operating as if they didn't exist? That is the sort of thing we have yet to learn. You may find some clue to it as you go on with your patient.

P: She was married three years ago and is now seven months pregnant. She showed a series of reactions to pregnancy: at first she wanted very much to become pregnant, but whenever her menstrual period was late she got into a state of panic; when she in fact became pregnant she was very afraid; she was afraid of having a deformed child; she thought she was too old to have a baby.

B: Two points occur to me. Why didn't she feel these anxieties much earlier? And how sensible of her to feel them now. She seems to be showing signs which I think are very reasonable. If I were a woman and had to give birth to a child, I would be scared out of my wits. There are a few classes of people, like doctors and airmen and sailors and coal miners, who face the issues of life and death all the time. It is often difficult for patients to realize that they are dealing with these fundamental issues when they say they want babies or don't want babies. When I say, 'life and death', I don't mean 'death', but *life* and death; it is the birth of the individual that is also the continuation of the race itself.

From what you have said, I would think that this patient is making remarkable progress and is very well adjusted to be having fears and anxieties that are so often denied. But what is to be said to the patient who pushes it forward to you as a sort of neurotic symptom? I pose the question, but let us leave it alone for the time being and continue with the story.

P: I could never understand why she sporadically mentioned that she felt better. I am not sure that getting pregnant is something I could consider as a form of progress, in spite of the anxiety and fears she was expressing.

B: It might be helpful to consider the possibility that this bother about the periods, pregnancy, and so on, can all be a sort of unconscious sarcasm. It is as if she didn't want to triumph over the analyst,

but if she did she could feel that of course she's better, she's fitter and fitter. She is able to do this wonderful thing, but naturally a poor feeble creature like a male would be upset if the woman was pregnant, if her periods stopped, or if she had some sort of physical development, because that is the way men are – stupid, silly creatures who can't understand that a woman could do this thing. It is complicated because she is also frightened. She can be feeling well *and* be feeling that it is a dangerous situation. The man may not be able to tolerate the fact that the woman can be pregnant, or he may have a breakdown because he is so anxious and frightened about the pregnancy. We need to have more analytic understanding about the pregnant woman; we also need to know more about the mental reactions of the pregnant male. The generating unit of the human race is a couple, so when a couple are having a baby, the male may be tempted to get as far away as possible from the sexual pair as he can – even though he is one of them – or he may stay it out. In analysis you get only one side of the picture presented to you. This patient is feeling as if you were the husband; she is also feeling that you are the analytic husband in the sense that you may not be able to believe in the possibility of psychoanalytic pregnancy, that there can be such an outcome of the psychoanalytic intercourse that one could legitimately talk about 'a psychoanalytic baby'. She can be afraid that her analyst will disappear because she is pregnant, saying, "Oh well, if you are pregnant, if you're cured, if you've got a husband, good-bye, I'm going"; or that the analyst might get frightened and say, "You must be psychotic, you must be seriously disturbed to think you are pregnant. You had better go into hospital and have surgical intervention". I'm exaggerating it for the sake of clarity, but it does arouse a certain degree of anxiety in her, and she is afraid of what it arouses in you in the way of envy and hostility and fear – especially if you are able to achieve a successful analysis.

P: She was anxious only during the first three months of pregnancy. Then she showed signs of miscarrying and had to stay in bed for several days. After that she began to feel very attractive and calm, and told me that she even forgot about being pregnant. I got the impression that this was actually so.

B: All one can do is to go on analysing. But I think that she does produce this complex relationship; she does in fact dare to tell you that she is pregnant and even that she has various anxieties. And

since you have not got rid of her, she is encouraged to come again and to go on coming.

Do you know anything about her husband?

P: The impression she conveys about him is that he is as ill as she is, and that they live in a state of rivalry, one trying to control the other. She masturbates a lot and therefore they have less sexual intercourse.

B: The adolescent patient can remember very well what it is like to be a child because he still is, and he can know a good deal about what it is like to be grown-up because he is. So at that stage we are dealing with two peculiar objects. Much the same thing happens over and over again at different stages; it can happen with the couple because the two may never have individually been married before. They both think they know all about sex, but in fact they don't; they only know what they *used* to know – masturbation and all kinds of sexual activities with which individuals of both sexes are quite familiar. One could say that potentially a married couple is being born, and a sexual pair is ceasing to exist.

P: I would like to tell you something of the last session. She was already talking when she came into the room – this is a very common occurrence because she can't keep quiet, she keeps on talking about routine things for the whole session and leaves smiling and looking very happy. If I interrupt her she gets very irritated. I asked her, "What are you wanting to tell me when you speak about these things?" She replied that she didn't know, but if I wished she could go away because she was very irritated with her husband with whom she had had a quarrel that morning.

B: The test seems to be whether you can stand this flood of domestic trivialities.

P: She gives the impression of being fascinated by trivialities.

B: I think that perhaps you are felt to want something grand like a domestic disaster. desertion, the break-up of the family. The analyst, like the husband, cannot do anything wonderful like producing a baby, so there is every chance of his being so jealous or so envious that he would like, even if he cannot produce anything else, to produce a disaster. So her reaction is, "Well, if that's what you like I'll clear off and bust up my family – *then* you can feel what a wonderful analyst you are".

6

Presenter: I have a patient who behaves as if he despises me deeply. This situation is very painful for me. I feel I ought to have been able to show him my limitations.

Bion: Why do *you* want to show your limitations? The *patient* should state what he thinks your limitations or capacities are. You are analysing the patient; therefore you want to know what the patient thinks. I don't understand the point about the *analyst* making his limitations known.

P: The patient acts as if I had no limitations at all.

B: When a patient comes to an analyst, he should learn something about himself. The fact that an interpretation is often given in terms of the relationship with the analyst is not because the analyst is of any importance; it is simply because the analyst is trying to draw attention to the character of that particular person who is showing certain beliefs about the analyst. For example, if the patient displays, or demonstrates in some way, feelings of contempt or hostility for the analyst, the important thing is that it tells you something about the patient. If a patient says that he is very grateful, that doesn't really tell you anything about the analysis or the analyst. But it does tell you a lot about the patient. It tells you that the patient is *capable* of feeling grateful. Another patient, by contrast, may be incapable of expressing any gratitude because he is so jealous or envious that he never expresses gratitude at all. One gives interpretations like, "You are feeling that I am . . "., not because the analyst is a person of any importance, but because it gives the analysand a chance of recognizing what sort of person he himself is. If he is capable of love and affection and gratitude, it is important that he should know that – and so on through the list of his capacities and incapacities. In analysis it is

possible to see the kind of relationship that the patient is able to have with somebody who is not himself.

P: So if the analyst makes a mistake, it is important to analyse not the mistake, but the patient's reaction to the mistake?

B: That's right. We all know that we are human beings; one thing that is absolutely certain is that we all therefore make mistakes. If we didn't, it would be very difficult to account for the chaotic mess in which the world is today. It is run by human beings who are making mistakes the whole time. Take this particular patient: if he cannot have a relationship with people who make mistakes, he will have to give up having anything to do with human beings. But if he does want to mix with human beings, then he will have to learn how to associate with people who make mistakes and are always in trouble of some sort. What one must draw attention to is, "You are very upset because I . . .", whatever the mistake was. "This is again the same grievance – you are not able to forgive the fact that, as far as you are aware, I appear to have made a mistake".

P: But isn't it very comfortable for the analyst to take this approach – not to stop to think about our mistakes?

B: I don't think it is true that we don't stop to think about our mistakes. Most of us agree that we ought to know as much as possible about ourselves; if we have the time and the money, we might be able to afford to go to an analyst. But even suppose we are wealthy enough to do that, the amount of time available in the short space of one life is very, very little. Although we try to be aware of our weaknesses, it is extremely unlikely that we ever would be, even if we were analysed all the time. While an analysis is going on we are changing; it is very doubtful that any analysis could keep pace with our own characters. So we become people who are able to make still further mistakes. I don't think we ever *believe* that as we grow older we become wiser – we only *hope* so. We can only hope that by and large the community becomes wiser. Analysis has had a considerable effect on the general attitude towards certain problems in the last hundred years; people have a less exaggerated or rigid view of themselves and other people.

To return to your problem: what mistake have you in mind with regard to this patient?

P: I was paying too much attention to what the patient was saying rather than what he was doing. His attitude – showing no respect

for me – worried me very much, and I was curious about my own reaction.

B: That may be so, but it is the kind of thing you can take up with your own analyst or in some other situation. Suppose a trained nurse finds, when an accident or disaster occurs, that she has to carry out some emergency procedure on the spot without any of the usual equipment. Then suppose that same procedure is carried out in a properly equipped operating theatre with adequate nursing staff and a surgeon skilled at that particular operation. Of course it would be done better. But what is a nurse to do when she is confronted with a man or woman who has just been shot? All that she can do is something in accordance with what she knows about medicine. It is no good her regretting that she didn't take medical training – that is irrelevant. The only relevant thing is to use her common sense and do what she can to assist this particular casualty. In England you cannot take legal action against a doctor because he has failed to cure a patient; the failure to cure is not a crime – even being an incompetent doctor isn't a crime. What *is* a crime is to be negligent; you can bring an action against a doctor on the grounds that he didn't try. In psychoanalysis it is one's obligation to *try* to help – you cannot be under an obligation to help. You can try to draw the patient's attention to what you think is the truth or a fact, but you cannot consider that you are obliged to succeed. The mere fact that somebody else might or could succeed is irrelevant. It is a painful situation over and over again; we can be aware that we don't know enough, or that somebody else would know better how to deal with a particular problem. But I don't believe that we would be in any less difficult a position in any other job. While it is dangerous to be so complacent that you are completely satisfied with whatever you do, it is equally dangerous to believe that you are a bad analyst simply because the patient is having a holiday enjoying attacking you. This is something that cannot be completely dealt with in the course of your own analysis, but can only be learnt *after* you have become qualified and have finished your own analysis – then you have a chance to find out who you really are.

This patient, if I understand you rightly, is behaving as if he knew the right way to treat his analyst. But on what grounds does he think that is the right way to treat an analyst, or somebody who isn't very good at his job? Even if I am an incompetent surgeon, for example, to treat me with contempt or hostility is not necessarily the best way

to behave – in fact I think it is doubtful if it is the right way to treat anybody. If possible, you ought to draw attention to this fact: "You are feeling that, compared with you, I am a very unsatisfactory person. But you also seem to feel that if you are so superior to me, the right thing to do is to show your superiority by being rude and contemptuous". That would give him a chance of seeing how he feels about you. And if he is contemptuous and hostile to you, he is probably very much the same in other situations. It also gives him a chance to compare that sort of attitude with any other ideas he might have.

P: When I pointed this out to him he became very emotional, covered his face with his hands, began to sob, and said, "I am lost".

B: That is a very striking response. This attitude of superiority and contempt is not felt to be good enough, but then he is afraid that if he gives it up he is lost. It is hardly a qualification for being superior because it is obviously very vulnerable, very feeble. Of course one's object is not to make the patient cry, but to give him a chance of understanding what he has just said. This is what makes analysis so very painful for the analysand. If this patient cooperates, his facade may crumble; it is very difficult for him to stand being seen for what he is. There are patients who won't lie down on the couch but want to sit facing the analyst. They don't realize that the couch is there not in order to show how inferior they are, but because it might be easier if they use it. A patient who does that will often resort to wearing dark glasses, or to turning away uneasily, or to finding some method of avoiding being regarded – either physically or mentally. The patient discovers that although it appears easy to have an analysis, in fact it is very unpleasant to be in a situation where there is another person who has some respect for his personality and is prepared to look at it.

7

Presenter: The patient is a forty-year-old unmarried man, a diplomat. He came for analysis six months ago, not knowing what he wanted. He presented some physical symptoms and had the impression that he couldn't deal with his problems. His physical symptoms were migraine and gastro-intestinal disturbances like colic, constipation and digestive disturbances. This material is from the most recent session, last Saturday.

He lay down, started to talk, and told me he had had a dream. He dreamed that he was in hospital having an operation on his haemorrhoids, and was very worried because he wanted an English anaesthetic used. After he woke up he tried to work out the meaning of the dream, but came to the conclusion that he couldn't understand it. It confused him because he had already had an operation for haemorrhoids last year. He had a friend (who was also having an operation for haemorrhoids) who had told him, "I hope they use the kind of English anaesthetic that makes it easier to evacuate afterwards". Since he was confused about the dream, he decided to leave it to be analysed together with me. He was afraid to go on thinking about it because he felt he would become more confused. I said, "You were afraid to go on dreaming".

Bion: Were you intending to stop analysing him?

P: No.

B: How often were you seeing him?

P: Four times a week.

B: If this was the Saturday session, when would you see him next?

P: Usually on Monday, but last Monday he was not well. He

had in fact asked me to change the Monday session to another day because he is often too busy on Mondays.

He agreed that he was afraid to go on dreaming because he knew he might understand the dream, and even if his understanding was wrong, it would still be something that would have a meaning and so be analysable – he would rather come to an understanding of the dream with me.

B: He seems to have some doubt that there would be any free associations, but also some fear that there might be. This point is of some importance generally: a psychotic will very often have a dream that has no free associations, so the dream is useless. This patient's dream would be similarly useless if there were no free associations to it. But he *is* associating to it, and there is consequently some anxiety about what might emerge. Of course, a great deal depends upon what sort of job he has. As a diplomat he is supposed to keep confidential information to himself. So one of his problems is how to have an analysis and keep you correctly informed, and at the same time keep secret affairs secret.

M: Why did you ask about the termination of analysis following the material about the operation for haemorrhoids?

B: Because he is indicating that he is going to lose something or have something taken away from him. He is going to be operated on, and something is going to be removed from one end of his anatomy.

P: Two things are linked with his anxiety: one is the fear of being confused with things like dreams; the other is the fact that he has already been operated on for removal of the appendix. He came for analysis just after the doctors had recommended a laparotomy because of his digestive problem. He was afraid and didn't agree with the medical opinion.

B: He can't believe that it would be an operation that would be of use to him or he would agree to it. I think his fear is of losing something valuable. But a good deal depends on this 'English anaesthetic' which enables these removals to take place without his being aware of it. He can't make up his mind whether he wants to be aware of this loss, or whether he wants to remain unaware of it and just allow the loss to be sustained.

P: He said he thought his dream was related to something in the analysis. I told him that he already knew what kinds of anaesthetic

there are for physical pain, but he did not know what kinds of anaesthetic there are for mental pain, or even if there are any.

B: I think the anxiety here is that his analyst may really be on the side of some sort of dangerous organization, or of people who want to take something valuable away from him.

P: He told me some time ago – and I knew it was a fact – that he is very rich and owns a lot of real estate. His job as a diplomat is not a very well-paid one; he only holds it as a sort of security because he is afraid that a revolution might cause the loss of all his other possessions.

B: Even rationally it raises a serious question as to whether people who are in positions of responsibility or power should be allowed to have an analysis, because they may part with information of great importance. It seems to me that something has happened which makes him afraid of associating both with his analyst and those with whom his analyst associates. His analyst might be a communist, or he might be a capitalist, or he might be in the pay of a foreign government, or he might be in contact with spies. For example, if the patient knew that you were associating with me, then he might be afraid of what sort of information could be passed on to a foreigner. There is a danger, from his point of view, that he may either have to part with his job or part with his analyst. It depends on what other people think of his associating with a psychoanalyst. In this situation I think you have to consider seriously this problem of the traitorous activities of certain people. How is he to have an analysis without at the same time running the risk either of actually being associated with a traitor, or of being accused of being associated with one?

P: His object relationships are curious. Although rich, he earns very little in his job; sometimes he has to telephone his mother in New York to ask her for money; or he asks for money from his chauffeur, an old family retainer on whom he vents his hostility. If he wants to invest in a building, he keeps postponing the business with the lawyer until the very last moment. He finds no pleasure in his work – he only works because it is necessary for survival. But since he earns so little, owns so much, and has no pleasure in working, he doesn't know why he works at all.

B: One of the earliest noticeable forms of work is having to urinate and defecate. The other sort of work – at the breast for

example – is very rapidly rewarding. If things go well the baby sucks at the breast because it is so obvious that it gets an advantage out of doing so. That doesn't apply to the workings of the alimentary canal; it may not be at all obvious to the baby why it should have to use the pot. For one thing, there can be painful feelings about actually passing a motion, especially if the baby holds its faeces to a point where they become hard. It is something very nearly like being bitten at that end of the body.

Bringing that back to the present: the difficulty is to know what is going on with this patient. One could say that if he keeps all this money to himself, then he fears having to part with any of it because he would expect it to be very painful mentally and physically.

P: I told him that he seemed to use his mind like an alimentary canal, to absorb things and to expel them. This made him very confused. He was silent for so long that I asked him what was the matter. He said, "Lots of things come to my mind, but since they are meaningless I try to avoid speaking about them".

B: He is reserving the right to retain various thoughts on the grounds that they are of no importance – a very common thing.

P: I suggested to him that he was keeping to himself things he didn't want to evacuate.

B: I think that is right. He *is* retaining material. But how does he know that it is insignificant and unimportant?

P: I said that because he didn't evacuate he couldn't get any help or relief.

B: In either case he cannot: if he tries to keep all this confused stuff inside him, then he feels that he has something very bad inside; on the other hand, if he talks, then the analyst can see how confused he is. So he is anxious about what you would say or do if you knew this. In a way it is simpler if he can make it clear that it is your fault that he is confused – you can be blamed for the confusion. Otherwise there has to be some other explanation, and there is no knowing what your reaction might be to confusion.

P: He tries to avoid this confusion by a belief he has that he can stop thinking – he only has to follow the thought of another person. He suggested that this person would be me.

B: I have no doubt that he found a way of coping with the early, primitive situation; patients can either become 'constipated', and so avoid having the painful experience, or they can become, as it were,

'diarrhoetic'. Suppose he keeps what he knows to himself: then he is really putting a stop to analysis. On the other hand, if he cooperates and talks freely, then I think he is afraid that it becomes a sort of verbal diarrhoea, he is afraid of losing everything. In some ways it is felt to be like not just parting with his confusion and other rubbish, but also like losing part and parcel of his own body. In primitive terms, there is a fear of either being constipated, or of losing everything including a sort of penis. It is true that there can be the rational fear of losing all his money – after all, money today is supposed to have a kind of potency; we usually use it to do something with.

P: I have a feeling – corresponding to what you describe as 'diarrhoea' – that he cannot use his mind to preserve his money. At the same time he is very afraid of change. For example, he travels all over the world to buy paintings, but he never hangs them because he is afraid that after all he might like to change them and then it would cause him so much trouble to take them down and put them somewhere else – he would rather leave them leaning against the wall.

B: In this respect he is using the pictures as if they were a form of currency.

P: When he returned from Italy he brought some Persian rugs which were later stolen from his apartment. He did nothing about the robbery – he didn't call the police or notify anyone. He feels uncomfortable about his inability to preserve these things.

B: These pictures are undoubtedly felt to be something valuable. I think he also feels that his pictorial ideas could be useful. But in fact he told you that he didn't mention them because they are so unimportant. So all these ideas, or potential ideas, present their anuses – not their front views; those are facing the wall. So the ideas he presents to you are felt to be unimportant because they are only like the products of the anus.

P: I would like you to explain the meaning of the 'English anaesthetic' which is not to be used during the operation to obliterate pain, but afterwards so that the patient can evacuate without pain.

B: The patient's concern is how to have a painless analysis. He feels that it is all right to talk about his dreams because they are of no importance; free associations are equally all right because they are harmless rubbish. In other words, if he told you something that really mattered, then you might use it for your own purposes. Even consciously there can be an anxiety of that kind: people do make use

of the information they are given. It is only in analysis that we are particular about that; it is considered to be a serious matter that the analyst should be scrupulous about the use to which he puts information he gets in analysis, and not to take advantage of the analytic situation to make use of such information for his own private purposes. This patient's difficulty is this: he knows that he comes for analysis for *his* own private benefit – after all, what else could he do?

8

Presenter: This is a case which has already been discussed (Seminar 4). I would like to mention the change that occurred between that session and the most recent one. The patient began to move more freely after I mentioned envy in the interpretations. She lay down on the couch, and although she was silent as usual, I noticed that she was moving. Instead of just lying still, she seemed to be trying to find a comfortable position and was therefore moving her whole body. I also had the impression that she was mentally more mobile. After a silence of about fifteen minutes – the usual length – she said, "I feel untied. I recognize myself in these bad things I think and feel, like envy which makes me feel destructive".

Bion: From the negative point of view of the patient, I think she is describing a fear of the loosening of whatever it is that holds her together. So although there can be the comfort or relief of feeling less rigid, more mobile, there is also the anxiety that whatever binds her together into one personality is disintegrating – as if the personality was no longer held in any tense structure. One of the advantages of the patient's being able to feel better – it is very difficult to say what is meant by that, but it usually means some nice feeling – is that it gives a certain degree of confidence to go on having more analysis if there appears, in spite of these horrible feelings, a loosening of the fibres; it is a compensation. It is also one of these situations in which the presence of the analyst is very important – one always assumes that, but sometimes it becomes more apparent. In other words, while the patient is having a horrible fifty minutes, it is helpful to have the analyst present who is not feeling like that in the same fifty minutes.

P: She experienced the feeling of being untied as something good, and she expressed the fear that she would lose the ability to become less rigid.

B: She can express fear in a number of different ways, but fundamentally the fear is the same thing that is in fact bringing her relief. I am sure she will show in some way that she is anxious about this situation even if she welcomes it.

P: She said she felt an intense hatred for herself because she was afraid of not being able to maintain this change. I had the feeling that I was excluded.

B: Even if the *analyst* is able to maintain it, that doesn't alter the fact that the patient is afraid that *she* cannot. So there is a great anxiety about this feeling that the analyst probably has something to do with it, and about what would happen if there was no analyst there. In what way did you feel excluded?

P: She said that although she was happy to feel untied, at the same time she felt surrounded by a shield. She said she was mobile inside her cast, but had this feeling of enclosure, of being without air, living but entirely bound in the cast. I thought she was talking about things which concerned not only herself, but also the relationship between us.

B: There is one way for the patient to deal with a situation like this: to make the movements of the outside – whatever it is – conform to the movements of the inside. And the same thing the other way round. If they conform absolutely, then there is no way of being aware of the uncomfortable conflict between the two. This state of affairs repeats itself in much less primitive situations in which the child is anxious to agree completely with the father or mother, or to get a parent to agree with what it wants. If it succeeded there would be no awareness of the fact that they are two different people. However, in view of what you have said about this patient, I am suspicious that this is something extremely primitive. It is quite easy to imagine – I don't mean therefore that it is true or correct – that the baby in the womb tries to conform to the movements of the mother, or that the mother tries to conform to the movements of the foetus.

P: She rejected my interpretation that she was giving the impression that she was being born.

B: In the course of analysis – and in the course of life at large – people experience many 'rebirths'. I don't know if it makes it any

clearer if you say there seem to be situations in which the patient emerges from one state of mind into another state of mind. In the analytic experience you have a chance of seeing something which appears to be that kind of event – this upheaval in which the patient's attitude or personality seems to be changing.

M: Referring to what you said about the patient making the movements of the outside conform to those of the inside, and vice versa: if the patient succeeded, the analyst would be deprived of working with the patient. Would it be possible to express this to the patient?

B: It is a problem to know how that is to be expressed. The individual has certain ideas which are brought into harmony with the accepted conventions of contemporary society. If, in that situation, the revolutionary communist is existing in a conservative society, then there is friction. That disagreeable situation can appear to be dealt with by making everybody communist – then all is well, peace and quiet, no trouble, no difficulty, everybody is happy and cured. Except that – as usual – there are always some people who rebel. They may be capitalists rebelling against this smooth, satisfactory society. Or some artist, painter or sculptor will rebel against the accepted conventions. Once the representation of the human form, as done by Praxiteles in the Hermes, is accepted, someone like Rodin wants to display not the classical, physical, external appearance of the human being, but something like the character or spirit. The situation repeats itself all the time: Rodin is the revolutionary; then he becomes conventional, everybody sculpts just like Rodin. Of course, they may sculpt *just like* Rodin, but they are not Rodin. The same with painting: everybody agrees what a beautiful man or woman looks like. Then there comes along a Picasso who draws people he says are men and women, but who seem to have no conformity with the anatomical structure with which we are all familiar. Then it becomes the accepted style to paint 'just like' Picasso.

What is the material in which *we* must learn to work? If we were teaching sculpture we could say, "You have to learn to respect your marble". A good sculptor must look with respect at his marble or clay, or whatever the material may be; otherwise he will torture and mutilate it into some unsuitable form. This respect can be seen in Michelangelo's unfinished work in Florence; figures are appearing out of the marble, still showing chisel marks.

What material does a musician work in, or a mathematician? What are we working in? What are we trying to make emerge? We hope that what will eventuate will be a human being capable of using his own life. That is why it is so important that the analyst should respect his patient, or at any rate be capable of *trying* to respect the person he is talking to. This is difficult when the patient seems to have no respect for the analyst; patients often consider it a sign of great inferiority to have to go to a psychoanalyst.

Somewhere in the analytic situation, buried in masses of neuroses, psychoses and so on, there is a person struggling to be born. It seems to me that the analyst's function is not to demonstrate all these neurotic and psychotic mechanisms, excepting as an incidental in the course of freeing the patient. It doesn't seem to be fanciful to say that just as Michelangelo, Leonardo, Picasso, Shakespeare and others have been able to liberate this mass of material, actual forms which remind us of real life, so the analyst is engaged in an analogous occupation – an attempt to help the child to find the grown-up who is latent there, and also to show that the grown person is still a child. These two might very well go together, not simply in order to make them indistinguishable, but in a creative or profitable manner. This patient is potentially a mother, but it is all covered up.

9

Presenter: The patient is a doctor, a pathologist, who has been in treatment with me for five years. During the first month of treatment he had frequent migraines which came at the week-ends. After the first month he became free of these headaches. Recently they appeared again.

Bion: Why did he come for analysis?

P: His chief complaint was difficulty in sexual relationships. He seemed to be very glad that his migraines stopped, but he was never interested in exploring the fact. He has occasionally mentioned it during the five years, but has shown no signs of wanting to go deeper into the matter. I get the impression that the headaches returned because we were dealing with envy in recent sessions. And I think envy also had something to do with their disappearance.

I thought the following session was interesting. He came in, lay down, and remained silent – which was not typical of him. Then he started speaking about his brother who is in analytical training. He had had a phone call from his brother who told him that he had just bought an apartment – he is very wealthy. The patient said he felt very envious and angry, but was nevertheless able to talk to his brother and even listen to him and learn something from him. The patient said he knew that envy was very destructive, and this time he had managed to control it.

B: What did he expect to happen if he didn't control it?

P: I asked him what he meant by controlling his envy. His reply was verbal silence accompanied by movements which he usually makes when he is anxious. He usually lies on his back; this time he lay on his side and kept moving his body. After a while he said he felt

very distressed and, "You are trying to confuse me because I wasn't able to control my aggressiveness".

B: Well, somebody seems to have been controlling somebody. He started off by saying that he was controlling the envy. Now it appears that one half of the conflict at any rate is inside the analyst. If he wasn't controlling envy, what was he controlling? And now, who or what is complaining about being controlled?

P: I wanted to find out by my question what was happening, what the patient actually did.

B: He controlled envy, and his envy is extremely annoyed about it.

P: I was trying to clarify what he had experienced while on the telephone.

B: What seems to me to be important here is that you have a chance of knowing what evidence is available. If I identify myself with the analysand, I have controlled the envy; if I am the envy which is being controlled, naturally I complain that 'the other' – whoever it is – is trying to control my mind. The patient says, "I control my envy". He also says, "The analyst is controlling my envy, trying to control my mind". Could anything be more infuriating than having an analyst who tries to control his envy? Is it any surprise that he is impotent when he is not even allowed to be envious?

There appear to be at least three people in this group: the controlling person who controls X's envy; X's envy which is being controlled by him; and the analyst. Are you reminded of any theories, interpretations – analytic or otherwise – which correspond to this peculiar situation which is not unusual in the consulting room? Is there any known theory in all these vast volumes on psychoanalysis which appears to match this story?

M: The triangular situation reminds me of the Garden of Eden.

B: Yes. Freud always seemed to insist that the hallmark of analysis was that it illuminated, or brought out into the open, the Oedipus situation. Can you match this clinical event with the theory about the Oedipus story?

P: I now have the impression that the question I asked the patient was inadequate.

B: If you had been practising analysis as long as I have, you wouldn't bother about an inadequate interpretation – I have never

given any other kind. That is real life – not psychoanalytic fiction. The belief in the existence of an analyst who gives correct and adequate interpretations is part of the mythology of psychoanalysis. I certainly would not be inclined to bother if you felt your interpretation was inadequate. I *would* be rather bothered if you felt it was adequate. The practice of analysis is an extremely difficult occupation and one which hardly provides space for dogmatic statements.

M: What remains for the analyst? Only feeling?

B: Practice – the inestimable advantage of having a patient who so far has continued to come. The analyst may not know much, but he knows more than anybody else about this patient; he knows what the facts are. When I talk about this patient, I haven't the advantage that the analyst has – I don't know the patient. But I can believe that if I were this patient's analyst I would have no doubt about the hostility of this statement that I was controlling his mind.

Another analytic theory which appears to me to be reactivated by this story I have been hearing is that of projection: I would be strongly suspicious that this patient was projecting onto me and – to introduce another theory – into me, a part of his own personality and feelings. I wouldn't want to engage in an argument with the patient – "You projected your ideas into me", "No, you projected your ideas into *me*", and so on *ad infinitum.* In my experience anything like that is a waste of time. But on the other hand I wouldn't want to let it be supposed that the story that *I* was controlling his mind was one to which I subscribed in the slightest degree. So this *theory* about projection – although I think it is applicable and relevant here – doesn't solve the problem when I am engaged in *practice.* The analyst is in the unfortunate position of having to give a correct interpretation, if he can, while being subjected to the patient's hostility. It is an advantage if he can remain detached from this situation in spite of being told that he is controlling the patient's mind.

Note that I mentioned two theories: one, that the patient was projecting *onto* me his own ideas and feelings; the other, that the patient was projecting *into* me his own ideas and feelings. The first is applicable to a relatively simple situation; the second is related to theories about the sort of patient we would call psychotic. I would want to put over to this patient that he is projecting something *into* me, while still avoiding the point I mentioned about it becoming a terrible waste of time having to argue about who said what.

I might say something of this sort: "These feelings that you describe appear to me to have a very long history; I suspect that the relationship between you and your brother goes back to when you first became aware of a baby brother at all. You seem to feel as if I were really a blood relation like an older or younger brother. Sometimes you feel that you control your envy, sometimes that you are the envy which has been controlled". I have no idea what the patient's response to such an interpretation would be, but I could guess. The advantage of analysing such a patient, if he keeps on coming, is that you don't have to guess.

P: The patient behaves as if *he* is the analyst; he explains his feelings with his own theories and presents them to me like an analyst. I try to ask the kind of questions that might put things into their proper place.

M: So when the analyst stops him with a question he is confused?

B: I think he *is* confused, and his way of dealing with that situation is by saying, "I'm not confused – I'm the analyst. I'm not confused – *he* (the analyst) is. He's the younger brother – I'm the elder brother". Having the experience of being treated like this by a patient is indeed an unpleasant and difficult one. But you have to be able to go on thinking while having all these accusations and projections thrown at you.

P: I get the impression that the patient wants me to keep silent because he is trying to avoid my being able to analyse him.

B: It is quite likely. But keep in mind the fact that patients don't know more about the job than you do. It would be ridiculous for a patient to maintain that he is a better surgeon than the surgeon because he has broken his leg, or because he has cancer of the colon. But it is common in analysis for people to think that, because they have neuroses or psychoses, they are therefore better analysts than the analyst. It takes time to become adjusted to the fact that in spite of learning a terrible lot about our defects, we are nevertheless in the position of being the analyst if patients come to us. On no account, therefore, is any useful purpose served by agreeing that we know less about neurosis than a neurotic patient does, any more than a surgeon is entitled to give up operating on the grounds that a patient with cancer knows more about cancer than he does.

10

Presenter: The patient is ten years old, the third of four girls, and has one brother. She came for analysis because the family was worried by the fact that she was getting very bad results at school. She was unable to remember the alphabet or to learn numbers; she pressed her pencils too hard and had poor ability in copying the letters of the alphabet. She underwent a test which confirmed that her spatial and temporal co-ordination was poor; it also revealed that she is very intelligent.

Her mother has twice had psychotic crises and was in hospital on both occasions. She is in a psychotic state almost all the time and pays little attention to what the children are doing. She has always complained about this child, saying that the other children are intelligent but that this one is dull and stupid.

Bion: Did you think that the account of her test fitted in with what you see of her?

P: Yes. She seems to have no conventional sense of time. It is difficult to follow her because in her play everything seems to happen at once.

B: So she tells you a very great deal in a short space of time?

P: Yes, especially by her actions – carrying her dolls from one place to another, going out of the room, coming back, and so on. She often shows also that she doesn't understand the limitations of space. She tries to go into the other rooms; she can't stand the limitations of the play-room. The main thing I noticed at the beginning of the analysis, and now in this last month, is that she loves to pretend that we are at school and she is the teacher. In this last year she has progressed slowly and she can now read and write a little. She likes to test me to see if I can write or if I know how to add. In the last

session she was trying to find out if I knew how to multiply. She used to be very severe, always threatening me, "You must do this", and "You must do that".

B: I think that what you are describing is an experiment to find out what happens if she isn't so strict; she can try being your mother if you will be her baby.

P: She feels that if she could imitate the mother, that would avoid further dangers?

B: I certainly think that she must be feeling that she missed the chance of growing up, of being the young mother. She hopes to have the chance of being the mother with you.

P: Recently she was very sad and depressed. I said, "Perhaps you could tell me why you are sad." She said that she would be having her birthday party in two days' time and she was sad because she had had a quarrel with her boy-friend. I pointed out that she had not mentioned this before. She said she had had this boy-friend for four months and two days. I continued to try to find out why she was still sad and why she thought she would not get back on good terms with her boy-friend. She said she didn't want him to laugh at her; he had also said that he wasn't in love with her any more.

B: What had made the boy fall out of love with her?

P: I don't know. This came up in the last session and was something new.

B: So she didn't tell you how or why they had ceased to be friends?

P: No. Here in summertime the children go to the beach and have many parties and the opportunity to play and be together all the time. They have a different life from small children in Europe; little girls of eight or ten years old go dancing and already have boy-friends.

Two things had happened which made the session important. One was that her eldest sister had been taken by the father on a business trip to Germany for a week; she was very jealous and upset about it. The other thing concerned her brother – the only boy – who had had special presents for Christmas (a tape recorder, for example) and she was very jealous. She usually complains very little, but on these two occasions she was sad and complained a great deal.

B: It seems as if she has never had the chance of working out her rivalry and envy – that is either her envy of others or their envy of her.

It is quite likely that the analysis gives her the first chance she has ever had to feel rivalry, jealousy and envy without it causing some sort of catastrophic reaction. How does she come to the analysis?

P: A chauffeur brings her – always the same one.

B: Does she ever refuse to come?

P: No, never. She likes to come; she never misses a session. At the beginning of the analysis she couldn't bear to see another child doing something she wasn't able to do or owning something she hadn't got; she wanted to do the same thing and have the same thing. When she was playing with me she cheated almost all the time – she couldn't bear to lose a game. In the last three months she has stopped doing this.

B: What do you think has happened? Why is she not doing it anymore?

P: While she was constantly playing with dolls – being the mother, having babies, feeding them – I tried to show her how much she needed to do that so as not to be envious of her mother and of me. Three months ago, after a vacation, she stopped playing at being the mother, and she didn't try to cheat any more in our games.

B: You are dealing with a dynamic situation with this child who seems to me to be prematurely and precociously intuitive. She was able to 'see' (in our sense of the term) much more than she was able to stand at a very early stage.

P: I would like to describe one of the last sessions of last year. She brought me a doll and put it by my side. She said, "Now, you cover yourself and stay there; we'll call the doctor; you are going to have a baby".

B: In this dynamic situation she feels as if she were growing up, as if a sort of analytic baby will result from this game she is playing with you. There is also an anxiety about what sort of baby this is going to be, what sort of baby she herself is turning into. It is complicated by her feeling as if she is turning into both a baby and a mother – she is *becoming* a mother. But if she allows herself to be a mother, there is the fear of what sort of baby she will have. I would have thought from what she has already said that her fear is that the mother will slip round, as it were, and become her baby. Will it be a good baby or a bad one? Putting it in other terms, she fears that she might turn into a bad mother – not a nicer person but a worse one. This is part of the problem of being a very intuitive child; she fears

the increase in her capacity to be intuitive because of what she might do if she was in the position of the mother.

M: I get the impression that she uses the consulting room rather than the analyst.

P: I agree. Last year she often played at taking trips, going in and out of the room with her babies. Many times she said the babies must go to sleep, and then she wanted to lock the door and stay inside, putting me outside for a couple of minutes.

B: Outside for what reason? What was your impression?

P: I felt that she wanted to stay inside feeling like a mother and maintaining that position with her babies.

B: One question is, are you to protect the mother and her babies in this room, or are you a bad, hostile object who will damage them?

P: Sometimes she experimented at hating me for a week or ten days, but then she would give it up and I was admired again. The wish for me to have a baby came later. At another time I had the impression that I was in the position of a maid – she called me to look after the baby or to give it medicine while she was shopping.

B: There has to be a good mother somewhere, whoever it is. But I think there is also this problem of the dangerous father, the envious or hostile one who is excluded.

P: The father first appeared in the analysis when he travelled to Germany. For about three days she pretended that she was the mother who was travelling abroad while the father was here in Brazil; they had long-distance telephone conversations. The only other time that the father has come into the analysis was during almost a whole week when she was pretending to be in the United States in Disneyland. She pretended to be the mother, accompanied by all the children, calling her husband long-distance and saying, "Oh my dear, you should come; we miss you very much; the children are so sad, you should come quickly". Then she told me, "He can't come – he's too busy. He always comes at the end of the vacation".

B: The father is apparently a good one.

P: Yes, he is.

B: The telephone makes it possible to have a contact with something she has forgotten or never really worked through properly. There is a 'getting into contact' with a love affair she hasn't had yet – with the father of the family. She may be aware of something *behind* the actual father and mother. It is the future casting its shadow

before, as well as the past casting its shadow on the present. From this point of view, going to school is for her a waste of time because it is not possible to see what the kind of thing she learns in school has to do with having babies. It is striking that in the analysis she seems to feel that *that* is what she wants, *that* sort of game is really necessary.

11

Presenter: The patient is an eight-year-old girl. She draws a great deal in the sessions. In the one I am reporting, she drew a house with a girl looking out of the window. There was a road passing the house and two people standing there playing instruments. They were playing some music that she had learnt at school, about a boy singing a song to his girl-friend.

Bion: How does she bring in this music? Does she sing it?

P: No, she explains it.

B: A sort of running commentary on the drawing?

P: Yes. I said, "You are telling me about things you like, such as having a boy-friend, but also something you don't like that you cannot keep". She erased the girl and the two boys, and then drew a girl sitting in a hammock slung between two trees, and the sun drawn with the face of a person.

B: What about the expression on the face of the sun?

P: It had no special expression. She erased the drawing again and drew small fishes in the sea and a fishing boat. Then a big arch at the bottom of the sea. She said the arch was full of hidden treasure; a thief had stolen it, had run away from the police, and had thrown it into the sea. I said she was afraid of the hidden things inside her, and afraid that I would not understand. She drew a shell and a necklace inside the arch, and a man swimming close to the arch. I asked her about the swimmer; she said he wouldn't find the arch because he was swimming with his head turned the other way. I said she was afraid that these hidden things might not please me and then I would not like her any more. Then she rubbed out the swimmer and re-drew him facing in the direction of the arch.

B: Has anyone any questions before we hear the interpretation? Where do you feel are the biggest gaps in your own knowledge?

M: I think we want to hear you.

B: Yes, I'm sure you do. I would gladly give an opinion but what do you think a supervision is? What is the object of the exercise? If I were analysing this child I would have no chance of discussing the matter with anybody; I would have to think of an interpretation and hope that it was on the right lines and related to the facts she was putting at my disposal. There is a great deal to be said for being an analyst, provided of course that one can learn how to be a better one. But is there any point at all in supervision? I don't think it is any worse than a scientific meeting which is hardly any use whatsoever. I can give a number of reasons why I think there is something to be said for them from my point of view, but what you have to consider is this: when you have very little spare time, can you really afford to spend such time as you have on scientific meetings, supervisions, or anything away from the actual practice of the job? What use can we make of *this* meeting?

M: We can exchange points of view.

M: I would use the Kleinian point of view in the session with this child; her relationship with her mother, primary objects –

B: I think I would do the same if I were tired and had no idea what was going on, and if this child wasn't telling me anything. If, in fact, the worst came to the worst, I might fall back on Kleinian theories, Freudian theories, Abrahamian theories, any theories.

P: It seems to me that the patient's anxiety is related to the primal scene; the girl looking through the window.

B: I do not disagree with you about that, but why musically, why sound? Why in drawing?

P: It suggested itself to me because it was a love scene.

B: I am not quarrelling with that at all. But what is this child trying to say to the analyst? And why has she to fall back on her capacity as an artist or a musician? I think this idea of the love scene or serenade may be important; and it may have been important to be able to draw it.

P: The feeling of a love scene is very strong because it has been in one drawing after another; she is maintaining a conversation through the drawings.

B: If the child is sufficiently gifted she may be able to make up for the difficulty in conveying to the analyst what it is she wants to communicate. That is why I ask: what is this child's language? To some extent it is complicated because she is obviously able to talk – she describes what is happening in the pictures.

P: She has the capacity for expressing poetry.

B: She has to use every capacity she has if she is going to talk to the analyst. She has to be able to draw; she has to be able to see; and she has to be able to give a verbal description of what she is drawing. Using all that, she still has a hard job to make clear her problem. I sometimes feel that a patient's job is made even more difficult because he or she has to get through the analyst's preconceptions.

M: Do you mean that besides the theories the analyst has, he also has preconceptions?

B: Of course.

M: Would you say something more about it?

B: If a young child came to me for analysis I would be surprised if she stayed in the room for more than about two minutes; I would expect her to feel that she didn't want to talk to someone who looked like me. But that might not be true; I might remind her of somebody she knows, like a grandfather who listens to what she has to say. So she might be prepared to tell me quite a long story in the hope that I would listen. That problem arises with every one of us. In fact one of the difficulties about undergoing analytic training is that we tend to forget that the real puzzle, the real mystery, is that anybody comes for analysis at all.

To return to this patient: she seems to feel that it is worth while trying to draw in order to tell you something. What vocabulary would you use if you are going to ask any questions? You certainly don't want to give the impression that it is a bad drawing, but it would be interesting to know what the sun is doing, or what its expression means. I am pursuing this because we can be reasonably sure that a child who talks so intelligently almost certainly was the observer of what you described as the 'primal scene'; a child or infant very early on gets suspicious about what is going on. If you cast your mind back to any occasion when you have seen a baby stare, you will recall the effect that it has – I have known a mother get quite anxious on being stared at by her own infant. Sometimes this stare seems to be 'what?'; sometimes it seems to be more 'why?' That is why I ask,

what is the sun's expression? I am sure that at some point it would be an expression of what her feelings were on witnessing or being aware of the parental relationship – although at present it seems to be more an observation of her relationship with her analyst.

What happened after she had drawn this picture with the sun and a hammock slung between two trees? Do you remember anything else about that picture?

P: In previous drawings there had always been a sign of being unable to sleep. But in this one the figure was asleep.

M: My phantasy is that she could go to sleep because she has stolen the mother's place.

B: There is always the chance that if you can have a phantasy it might turn into an interpretation.

M: I am doing a mental exercise for you.

B: 'Mental exercise' is right. Isn't it surprising that one might have to do a mental exercise for a child? There are so many people who assume that nothing could be easier than to bring up a child.

M: I think the 'mental exercise' is necessary because a child has very little capacity for symbolization.

B: I often feel that the same remark applies to psychoanalysts. I don't feel that a child is so lacking in capacity as we very often want to believe. In fact I think it is much more useful to consider the possibility that one does not know a great deal about this subject, and that even a child might teach us something if it could be persuaded to tell us a bit more.

I have quoted before from a letter Keats wrote to his brother in which he said it occurred to him what the great strength of Shakespeare was – he could tolerate mysteries and half-truths without an irritable reaching for certainty. The important point about that is the 'irritable reaching for certainty'. Pressure is put on us as analysts always to know what the problem is which is so obscure, so difficult to grasp, and which is unfolding itself in front of our eyes. This child is cooperative, friendly; she draws, talks, describes; one is bound to feel that one ought to know the interpretation. But the really important thing is that we should be able to watch this drawing, or join in the conversation, so that the child can have a chance of saying what she is able to see or feel or hear which we cannot. The 'primal scene' becomes extremely convincing when it is portrayed for you by a child; sometimes even the gifted grown-up finds a phrase which is

a short, concentrated description of exactly this scrutiny, this stare at the parental pair, or, to make it more vague, the sexual pair. This stare can either be at two parents engaged in some sort of sexual activity, or it can be a parent scrutinizing two children similarly engaged. It is worth searching your own experience to re-mobilize some of these possible expressions of that scrutiny, that threesome situation – the observer and the two observed objects. The exercise can be increased still further by considering what is observed. Sound? Sight? Smell? What sense? It would give you an enormous variety of what we call 'psychoanalytic interpretations'.

12

Presenter: The patient is a twenty-six-year-old man who has been in analysis with me for six years. He wanted to be analysed by me – not by anybody else. He was worried about his homosexuality.

His father owned a farm of thousands of acres, a large house, and was a very powerful, wealthy man. His mother was born in China, then went to Russia; from there she came to Brazil before she was thirteen. His father met her when she was about fifteen years old. She was described by everyone who knew her as a beautiful girl. She was always afraid that her son would be regarded as Chinese or Russian, not Brazilian.

He said his mother had a very easy delivery when he was born and he was breast-fed. His brother, who was born seven years later, became very ill and could not take the breast. The patient remembered being very anxious about this. He also remembered once trying to kiss his mother when he was eight or nine years old. He kissed her mouth, and she said, "No, you mustn't kiss my lips – that's not allowed."

He still feels like a father to his brother who once almost fell from an eighth-floor window when trying to cross from one window to another on the outside wall. Five years later, when the patient was under the influence of marijuana, he had been tempted to jump from the window of his home on the tenth floor. But he thought, "I am in analysis – there is hope in my life."

He has a great friend, a woman, who is an internationally famous painter. His mother is very jealous of this friendship. Once he invited this friend and her husband to stay at his farmhouse. His mother said, "This woman is very interested in you. I don't want you to continue

this friendship – it will lead to scandal – she will leave her husband." He says his mother has always been jealous of his friends.

When he was only ten years old, he suspected his mother of having a sexual affair with a woman. He became very anxious and started spying on his mother, even in her bedroom.

At about the age of thirteen he started to take an interest in men; he tried to have sexual intercourse with the maid's brother. He continued to have sexual relations with many young men until he met one whom he described as a new type of beauty; he said he was like Dorian Gray. This continued for two years, during the analysis. Then he told this young man, "I feel that we are becoming friends, and as your friend I won't have any relations with you. I never want to see you again." He offered him a large sum of money, but the young man refused, saying, "No, we are friends."

Next he had a sexual relationship with a young woman who was a well-known expert in manipulating the stock exchange. He gave her four hundred thousand shares to deal with and lost them all. He said, "Oh well, in a few months the shares we have will bring us in much more than I lost."

He is an accomplished painter, but he only paints ugly figures. For instance, a typist without hands; a violinist without arms. Each one has ugly features. The pictures are always black. Somebody asked him, "Why do you paint these pictures?" He replied, "Because I am an artist, and you know what 'artist' means – it means looking for beauty and looking for truth – and *that* is the truth about humans."

Bion: What do you think he comes to you for? He insisted on coming to you, whether you wanted him or not. Why have you got to see him? From your account of him, he has everything – brains, intelligence, money.

P: He came to me because he hates himself so much. He once said, "It is better to be a leper than to be a homosexual."

B: What does he mean by "homosexual"? You could draw his attention to the fact that this is a technical term. What is the evidence that he is homosexual? You could ask him that. And how does *he* know that he is homosexual?

P: The evidence he has is that he prefers men to women in sexual intercourse; when he was young he hated all women. He says, "I want company only until I have had intercourse – afterwards I don't want to see anyone."

B: Terms like 'homosexual' are no longer employed as technical terms – the are just part of the language people use over and over again; unfortunately the whole language we employ is debased. From one point of view there is absolutely no difficulty about a sexual relationship – children, even infants, have sexual relationships. So it is no particular surprise to me to hear that this man can have sexual relationships. The sexual relationship has become something which is easily done – like everything else he does. He prefers men to women. What of it? A great number of women prefer men to women. A sexual relationship is pushed into a position in which it matters very much whether he has one or not – which is simply not true; it is one of the few things which any animal can do. He is behaving as if he cannot have a sexual relationship, but his trouble is that he can. So I would like to consider what it is that he cannot have. Apparently he can have almost anything. What is it then that is arousing a feeling of despair?

Freud said, in *The Interpretation of Dreams*, that the symbols would change. Of course he was right. As a matter of fact the symbols which are employed by any particular individual are that individual's unique contribution. So when he is using a symbol, one must consider what that symbol symbolizes. In a sense he can solve this problem by having a sexual relationship like everybody else – 'homosexual', 'heterosexual'; these words are now symbols which have lost their original value and have new meanings.

This young man could have a sexual relationship at the age of thirteen; long before that there was no difficulty about using his genitalia. But there can be a realization that the sort of experience he had as a thirteen-year-old was not 'it'.

M: What is psychoanalysis for him?

B: Psychoanalysis is only another example of the sort of thing he is familiar with. In so far as it is just a conversation with somebody else, I think it is very unlikely to have the slightest effect upon him; he is unlikely to believe that psychoanalysis could do anything to alleviate his feelings of despair. But this peculiar fact that he picks on a *particular* analyst and insists on coming to that analyst, seems to be different from feeling that analysis is like everything else.

I think that this man has never been able to love and has never experienced being loved. But at the same time – and here's the puzzle – he realizes that there is something better than just fiddling around with men and women, having these easy sexual relationships.

Those experiences are always expressions of hate, and always lead to the emergence of hatred of the sexual experience and of the partner. I don't know why the vocabulary concentrates on this matter of a sexual relationship with the same sex, except that it gives a simple explanation which is no explanation at all. Sometimes a sexual relationship is called 'marriage' or 'engagement'; one is fooled into believing that the person is a mature individual. Whenever we have to deal with a patient who says that he or she is happily married, I think we always need to see if we can bring out into the open this element of hatred for the partner in the sexual experience. This is one of the peculiarities of a 'homosexual' relationship – it is unsatisfactory because the two always hate each other. I say 'always', but that is not right. You may come across two men or two women who really love each other deeply – for example, David and Jonathan. The mature relationship of passionate love between a man and a woman is something which comes very late, and it never ends – there is always more to learn.

M: I would like to know your opinion about a loving relationship between two people of the same sex who also have sexual intercourse.

B: I would have to see and meet those two people, and then I could tell you what my opinion was. This is the whole point about psychoanalysis. That is why I say, by all means read all these books and everything else you want to, but don't let it get in the way of your forming your own opinion of the person with whom you are dealing.

P: A few weeks ago the patient said to me, "Doctor, why aren't I interested in women as other men are?" I said, "I think you are doing what you did with your man friend – you recognize that women deserve respect, and you see in each woman not the woman, but the man." He became very nervous and said, "I can't understand such things. If I see women as men, that's bad." He didn't come to the next two sessions; then he came again but didn't refer to the previous session. Later on he said he was very depressed.

B: This young man is told something about his sexual life, and his immediate reaction is, "That is terribly serious", as if he had heard some sort of bad news. In short, he is expressing his hostility to the analyst for telling him something. But if the analyst is telling him something which is true, that is no particular reason for hostility. So even the *analytic* relationship is one in which you can detect this same hostility even though it is only verbal intercourse which takes place.

The seriousness of this condition is that sexual activity is probably the most intimate method of expressing love and affection. That is why it is so serious when it is debased, when it becomes the kind of thing that can be had with anybody and everybody.

13

Presenter: This patient originally came for five months and then left on his own initiative because he was suffering from a severe case of obsessive neurosis: it took him so long to wash his hands – an hour – and to take a bath – four hours – that when he arrived for his session there were only five minutes left. A year later he returned and started again. We agreed that if he didn't come for at least half an hour of each session until the end of January, then I could not continue the treatment. He was unable to meet these requirements, so the sessions ended on January 31st. I told him that we could continue when he thought he could manage to arrive in time to have at least half an hour of the session.

The session I would like to present occurred two months after the analysis was interrupted by me. It was possible for me to see him because it was Easter week and I had a free hour.

Bion: I would be doubtful about interrupting the analysis. It seems to me easier to say right at the beginning, "If I have a vacancy I shall want to see you X times a week, and I would like you to conform to my holiday arrangements." You can say you will expect the patient to pay if he takes time off; you expect the time you make available to be paid for. What the patient does with that time is another matter. This patient could say, "Well, I come regularly; I do the best I can; I come so many times a week – I do everything." You can agree to make your time available for the time being, but you cannot tell the patient what use to make of it.

M: Isn't there something implicit in the concept of work that both people should work together – actually work?

B: You would think it should be so, but it very often isn't. The background of this could be that the child believes that the parents

must look after it. But in fact they don't – that is why there are children who are abandoned. So I don't think you want to appear to enter into a contract which you cannot in fact keep. You can try, *if* you get some help from the patient, but you don't want to get edged into a position in which you have said that you will cure him or do something for him no matter whether he helps or not. He may not come, or he may be thirty minutes late, or he may come and say nothing. But you cannot contract to help the patient whatever he may do, any more than you can contract to bring up a child however hostile or unhelpful it is.

M: Would it be worth saying to the patient, "You are sacrificing yourself", or, "You are sacrificing the session"?

B: I wouldn't say that. I would say that he seems to feel that he has so much time and money available that he can afford to spend it in that way.

P: Another condition I had made was that he should leave his parents' home because of his mother's hostility towards him. When he lived with other people he managed to keep appointments. When he arrived for this session (twenty-five minutes late) he was already living away from home in a boarding house. The owner was a neurotic woman who had many difficulties in bringing up her own children. He was not allowed to use the telephone or to occupy the bathroom for long periods. The time he took to do things created a climate of tension between him and the landlady. For example, he wanted to heat some milk, but she wouldn't allow him to; they started quarrelling because he insisted on heating the milk, saying it would only take a minute. So she threw a plaster statuette at him – which he avoided. Then she tried to throw a chair at him. One of her children arrived and made peace between them, but the landlady told him to leave. So he went to his room and started packing. But as usual it took him a long time. After packing, he went downstairs and asked the landlady to give him back half his month's rent deposit. She said she would only return the money if his parents came to fetch it. Then she put him out in the street. He kept protesting that this was impossible because there was a contract between them and he had paid his account.

B: What contract would there be in childhood or infancy? How would he pay? It is all very well for him to say he paid the deposit and so on, but what deposit did he pay his father and mother? What

contract, in other words, is there in which the parent is bound to bring up the child?

P: I told him that he was treating me like the landlady. He now wanted *me* to pay a penalty for breaking the contract.

B: What contract is there with the analyst when the analyst isn't even a father or mother? Yet he is expecting you to do something which nobody has done so far.

P: After I gave this interpretation he said he couldn't understand, so I repeated it. I added that this situation is one already well known to him; he feels he is owed something by others; they should have patience with him and pay attention to him. He feels that these things are owed him because he was ill-treated by his mother.

B: But they aren't; nobody owes anybody a happy life or a proper up-bringing. The only place where he gets anywhere near it is with the analyst, and there he expects from a complete stranger something which nobody else has done.

P: I thought there was a connection between what he said and the milk he wanted to heat; it was in two plastic containers in the refrigerator. I suggested that he felt he wasn't getting good milk, that the milk his mother gave him was cold.

B: But suppose it was warm: who has warmed it? Whose contract is it to warm it? Where has he got this idea from? We hope to get some cooperation from a patient, but we don't know why this is expected. The only contract that the analyst enters into is that he will do his best – not that he will be successful.

M: Is this not a case of infantile narcissism?

B: The point is, what does it look like in the session? Where does his right to be loved come from? Why should any mother love her baby? Why should any child think the mother or father owes it an education, an up-bringing? You could draw the patient's attention to this. "You are talking as if somebody had entered into a contract to give you a happy life. But we don't know where you get that idea from." Patients will often say all sorts of things about what bad fathers or mothers they have. All right. But then, where does the idea that there is a good father or mother come from? One can say why the patient does not expect to get good analysis or help but it doesn't explain why the patient thinks he *will*. I could go further: there is an idea here that somebody will pay for the analyst to be properly analysed and supervised and so on. But who provides an analyst with

the knowledge which he has to have? It is hard to say where this expectation comes from unless what the patient wants is a 'mother' who will look after him. There must be some reason why he expects the analyst to be properly equipped.

M: I am reminded of patients who say they didn't ask to be born, but since they are in the world they expect it to take care of them.

B: Quite. Even in the constitution of the United States of America there is the statement that every man has the right to be happy. However, when it comes to our job here, where do patients get this idea that the analyst will take the trouble to be analysed, educated, qualified and so on? And where do they think the analyst gets the money from? Analysts have to ask patients to pay not because we are trying to take their money away from them, but because somebody has to pay for all this training and education. In the meantime, this idea that there is a fate or god waiting to put right all the things that go wrong, can be a dangerous one. This statement, "I didn't ask to be born", is a complete repudiation of any responsibility. Who or what is this patient defending himself against?

M: Perhaps against the fear of what he will have to pay in return for receiving analysis.

B: If he makes good use of the analytic experience, then he is showing that his parents gave him something he can make good use of, so they can't be absolutely bad.

M: I think he would tend to preserve the idea of feeling hostile towards the parents.

B: It is quite possible; it would contribute to the need to go on proving that he has a bad analysis; or, if he has a good analysis, it shows how badly he was brought up because he has to have an analysis. We could translate this into technical terms such as, "This is the genesis of repetition compulsion". Your patient has to keep on coming time after time after time, and still has to keep on having a bad analysis. You can go to a lecture about repetition compulsion, or read about it, but it is very difficult to recognize the animal when you see it in analysis.

14

Presenter: The patient is a woman of twenty-six, an only child. She is a psychologist, has just graduated, and was sent to me by the Institute of Psychoanalysis. She started analysis, four times a week, about a month ago. Right at the beginning she said that what had happened during the last nine years of her life seemed to have happened only yesterday, and that she didn't pay much attention to anything before that. What had happened was this: nine years ago her father got into trouble with the police over an involvement with a fifteen-year-old girl. The patient heard the news on the radio and read about it in the newspaper. From that moment on she followed all the activities of the police and the lawyers – her parents never talked about it, but she knew everything that was going on. The family moved from one town to another, running from the police. Now the father is on bail awaiting trial. The mother married against her family's wishes; she was very wealthy, but the father was just a janitor in a building downtown.

At the beginning of the session I am reporting, she did something different from usual – before she lay down she looked at me and smiled. Then she said, "Today I just can't think about anything. Why is that? Yesterday when I left here I felt quite free."

Bion: It is as if she felt that nine years ago something emotionally important happened with the result that she has never been the same again. But with you just then, she was afraid that the same thing had happened again, namely, she smiled at you – and there is no knowing what troubles may happen now. In other words, it is felt to be typical of one of these incidents which are apparently of no importance, and yet it starts such a train of events that you can never forget it. On the other hand, if she isn't going to dare to smile at the analyst or other

people, that is also a desperately serious situation. One of the very early experiences that the infant has is of smiling. That often triggers off most surprising results: the mother or father at once notices it. "Look, the baby is smiling!" So in a sense this trigger action is felt to have inconceivable consequences. I would try to draw the patient's attention to that; "I think something must have happened which reminds you of that disastrous series of events. Perhaps it is because you smiled at me." Or you could just say, "It would be useful to know what it was that scared you so much. You are frightened that it triggered off an imminent disaster." A great deal of experience makes me suspect that this is something fundamental, as if the foetus was responsible for starting birth. I don't see any way of ever proving that, but I certainly find it useful to bear in mind as being the first instance, even before birth, of a sort of catastrophic event. Then come these later events after birth such as the smile – which, as you know, is called everything from a smile to wind or indigestion. There are other occasions – adolescence seems to me to be typical – when the person is child enough to know what it feels like to be a child, and is grown up enough to feel very grown-up. There are many of these stages in which people are accessible to feelings which may not be quite so noticeable at other times.

To return to your patient: there is this event nine years ago, and this event a moment ago when the patient looked at you and smiled. All you can do is to hear and see what happens next. In the course of your own analytic work you not only have to manufacture your tools with which you carry out the analysis, but you also contribute to what is already known and appears to confirm psychoanalytic theory, or may indeed cause psychoanalytic theory to change, to become more expressive. In other words, if the subject is growing, then the existing theory has to be flexible. We have to learn all these theories, but it is a perfect pest in the end. We suffer from 'indigestion' of theories and facts, until it is almost impossible to hear what the patient says. The trouble today is not ignorance of psychoanalytic theories; the trouble is so many theories that you cannot see the patient for them.

The advantage of having parents who are happily married is that so many fears and anxieties don't matter very much. If things go wrong, then there may develop an individual who appears to be able to laugh but never smiles; unless the stimulus is very great he can't overcome the inhibition to do something which is just a smile.

Patients over and over again are able to laugh but not to smile, or if they smile, their eyes are always unsmiling. As a matter of fact I think analysis frequently makes it worse – it shouldn't, but psychoanalysts themselves sometimes appear to be unable to enjoy life or to do the equivalent of smiling. It is almost impossible to describe this kind of thing, but the advantage of psychoanalysis is that you get a chance of seeing real people.

Most people don't mind whether their children smile or not – there is no point in talking about it. But with this patient it strikes you: *that* is important. It is not a matter of the slightest importance whether this is mentioned in analytic text books; what does matter is that this patient smiles and *you notice it.* That can be the beginning of a train of thought, a chain reaction with you.

This patient can be afraid that you will kiss her or start making love to her – or that you won't. If you don't, perhaps it is because you don't love her, or because you are angry with her for smiling at you. The whole trivial business assumes great proportions. But had that event not happened nine years ago, or had it been properly dealt with at the time, it wouldn't today be of such tremendous importance and she would not be living in expectation of an imminent disaster. I would be prepared to bet that almost certainly something else contributed to the problem before that event nine years ago, probably during infancy.

15

Presenter: The patient, who had been absent for a few sessions before this one, came into the consulting room and sat in the chair. She remained silent and appeared to be suffering some sort of anxiety. I told her that I sensed her anxiety and that she was consequently experiencing some difficulty.

Bion: Why did you say that to her?

P: I sensed an atmosphere of tension and anxiety, almost physically.

B: I was wondering why you felt it was necessary to mention it to the patient. I am not suggesting that you should or should not; I am merely wondering why you did.

P: It came to my mind, and I felt it was interesting to show it to her.

B: But why? I am not suggesting for a single moment that I am asking you some simple question.

P: I don't know how to answer it.

B: I think you are quite right, but it is a matter of some consequence because otherwise one gets into a habit of thinking that the important thing is to say something to the patient. But you were there and you saw her. I am therefore interested to know why you thought it important to tell her what you did. However, let's leave it aside and see what happened.

P: She smiled and said, "Yes, it has been difficult to come. It isn't agreeable here, and it's boring."

B: She doesn't have to come, so what is the problem? If that is all that is troubling her, she only has to stay away and do something else.

P: In fact I asked her, "Why do you come?" She replied, "It is less difficult now than it was at the beginning, but I thought that this was

the time of day to be relaxing. I want to give up analysis and take a painting course where I would be more gratified."

B: Why not? It only intensifies the mystery as to why she had turned up at all.

P: She said it was a long time since she had done any painting; a course would provide her with the company of highly qualified people.

B: All this seems to me to be a very good reason for going to a painting class, but nothing whatever to do with her presence in your consulting room. In fact the only thing I gather she has said so far explains why she should not be there – not why she is.

P: I said I thought it was hard for her to come to the sessions because she did not want to admit her difficulties in the relationship with me, and because she did not like her own behaviour.

B: Why do you think she would like to be any different? In any case, what is stopping her – if she wants to be different, why shouldn't she?

P: It seemed to me that she could not tolerate feeling anxiety in front of me, that she was perhaps ashamed.

B: But I imagine there is a door to the room and she can walk out if she wants to. If she doesn't like your company she can find others in the way she has already said. It still doesn't explain what she is doing in your consulting room. It seems to me that you are trying to find an excuse for her, but I don't see why you should, and I don't see why you shouldn't expect her to say why she has come.

P: She thought about what I said, and then she replied, "I have always been like that; I have always liked to be the best. When I was a child in school, I was friendly with the headmaster's daughter. We were both supposed to recite a poem at a concert, but when the time came I couldn't say the poem because I was afraid of not doing well in front of the audience. And then I cried because I felt the teacher had trusted me and that she was disappointed in me." I told her that it seemed that she wanted to be my best analysand, that she wanted to have no difficulty with the analysis, no anxiety.

B: But she hasn't said that you are her favourite analyst. And you have said that in many respects her company is somewhat deficient. For one thing, she hasn't turned up for a number of sessions; I would like to know why. I would also like to know why she *has* turned up, who she thinks the analyst is, and who she thinks

she is. I might say to her, "You are very frank – you have told me that you find me boring. Do you tell most people this? Or is it the sort of comment you reserve for a psychoanalyst?" I am not saying this because I think it is very important with regard to this particular patient, but because you are liable to lose sight of this fact. A patient might come and use a flood of bad language, or draw a lot of funny pictures if he was a good artist, or bring a powerful musical instrument. Then it is sometimes useful to say to the patient, "You have just . . .", whatever it is. "Do you do this with everybody, or do you come and behave in this way only with me? If so, why?" You don't want to scare the patient, nor do you want to give the impression that you consider yourself to be a doormat should anybody want to wipe their shoes on you. After all, I take it that you intend to be an analyst all your life. So it is a matter of importance how you propose to spend your professional life. Most of us have undergone a prolonged, expensive and tiresome discipline. Was that simply for the purpose of being regarded as boring, or of being treated as people of no consequence and not worthy of respect?

If you say what I suggest, it introduces an element by which it can be made clear to the patient that you are aware of the way in which she is behaving. I am not sure that your interpretations really give her a chance of understanding that you expect something of her – this is a matter about which you have to make up your own mind. We all spend a lot of time analysing unconscious motives, but this is another matter – this is a problem which arises when you make it known that you are available for consultation. Saying that you are available for analysis in fact says nothing, but it is a convenient way of making it possible for patients to express what *they* think you are. For example, does this girl think it is useful to have an analyst *in case* she might want to see one, or *in case* she is feeling like being rude to somebody? We don't know, but at least you can have an idea of how you want to spend your time.

We are liable to drift into analysis for no better reason than that we happen to be good at it. Most of us are good at something or another, but do we therefore want to spend the rest of our lives doing it? And can we really expect our husbands and wives to share such an occupation with us? The question is a far-reaching one. It has nothing whatever to do with analysis, but it has a great deal to do with real life. It is a sad and depressing fact that the analytic world is

littered with people who set up as analysts for all sorts of reasons, and patients who are in serious states of mind because of that simple fact.

It sounds as if this girl wasn't at all sure that either she or her friend wanted to be in the delightful position of being the teacher's favourite. I suspect that she is afraid that you don't really want to analyse her – whatever that is – but that you want her for some private purposes of your own; that you want either to be her favourite analyst, or her to be your favourite analysand. She may not be particularly keen on either idea. She may indeed know already what it is like to be expected to do or to be certain things which she herself has not chosen, but which have been chosen for her by somebody else – like a parent, uncle, aunt, teacher and so on – who treats human personalities as if they were available for any purposes whatsoever. Most of us are familiar with being victims of precisely that attitude; our fathers or mothers have a phantasy of wanting us to be great men or great women. Sometimes they dress up little boys like girls with curly hair; and little girls like boys with page-boy haircuts – you can continue the list for yourselves. So patients, without knowing it, are really hoping that we are different, that we have some respect for their personalities. Although they may treat us as if they have no respect for our personalities, I don't think I would be over-impressed by that. Some kinds of behaviour are intended to be evocative or provocative so as to stir us up and then to wait and see what we do about it. Your reaction to that situation (I am not bothering about your interpretations) seems to have been sufficiently reassuring to make her feel it worthwhile telling you something which she may never have dared to tell her teachers or whoever was favouritizing her and her girl-friend. Everything the patient says – especially in the early stages – is a statement which may tell her something about the analyst and, if she is lucky, may lead to her learning something about herself.

What the interpretation of this story is I don't know and don't care. But I *would* care and *would* concern myself with explaining to her why she has told this particular story to me, and what lies behind it. My guess is that a patient who hasn't turned up – and who *has* turned up in this way – is suffering from a very considerable misfortune. I don't know what misfortune, but she wouldn't be coming and spending all that time and money for nothing. So far she puts over what she does not want: she doesn't simply want some person who is going to produce the same boring old stuff; nor does she want somebody

who treats her as a favourite. That is vague enough in all conscience. But if this patient goes on coming to you, then it may become a bit clearer because material accumulates. At first it is vague and you have to fall back on theories, but each time the patient comes you will have more to go on. This story about her and her girl-friend will form the basis of an interpretation which you will give six sessions later, six months later, six years later. That is why it is so important to have your senses open to what is going on in your consulting room in front of your own eyes.

16 [1]

Presenter: The patient has been in analysis with me for six months, four times a week. When she started treatment she had some psychosomatic problems – haemorrhage and diarrhoea – and she was getting thinner.

Bion: Who gave it the name, 'psychosomatic'?

P: I did.

B: What did *she* call it?

P: She said that she was physically ill. She felt that the problems were related to various occurrences during her life.

B: She was simply complaining of a whole series of things? Anything from being anxious to having a haemorrhage?

P: Yes. She was anxious because she had had a year's treatment with a psychiatrist who had once kissed and embraced her.

B: Do you know the psychiatrist?

P: Yes.

B: This is a great disadvantage. One would like to discuss a particular patient, and yet one can get involved in the professional behaviour of a colleague. It's a nuisance, a real problem. At the same time there is nothing to stop stories being told about *you.*

There is a great deal to be said for conforming to a certain discipline. In England it used to be accepted that a male doctor never saw a woman patient without having a nurse present. That is quite impossible in analysis; it has to be a private relationship. You have to establish the sort of rule you propose to follow in your own professional life, what sort of relationship to have with the people who come to see you professionally. People who are already known to you, or have met with you socially, often want to come to you for analysis. How that is going to work out I don't know. But if someone wants

to have an analysis with me, I would like them to conform to certain standards; and I myself would like to conform to a certain discipline, certain rules of conduct. For this reason I would not like to encourage the idea that I was available for kissing or any other activity which might be perfectly harmless, and even proper in a social relationship. The analytic relationship is a different one; the job is different. In some respects I think it is fair to consider that an analysis is as serious as a surgical operation; the operating surgeon preserves a certain discipline. I have only known one case in which a surgeon seemed to be allowing himself a freedom of action and behaviour with catastrophic results. Not that the surgeon was doing anything improper at all, but he seemed to be allowing a certain frivolity in the course of the operation – conversation, people joking. I think they were terribly misled by thinking that it was a very simple operation. So it was. But the patient, a child, equally simply died. Suddenly, in the middle of this somewhat easy atmosphere in the operating theatre, tragedy occurred. Emergency measures were immediately thrown into action, the whole atmosphere changed – all of it too late.

That is why I cannot admit that there is such a thing as a 'simple' psychoanalytic case. I have heard this sort of statement: "Students ought to be given only easy cases." It is sheer nonsense – I have never come across or heard of a simple case – never. Take the case you are presenting: the last thing I would dare to think is that it would be simple. In some respects I would far rather you had a complicated and horrible supervision than that you had a horrible and complicated analysis. So by all means let us get the worst of it into this situation, not into the thing itself.

P: The patient said that when the psychiatrist kissed her she felt that something exploded inside her like an atomic bomb.

B: Shall we go direct to the most recent session now?

P: This session took place the day before yesterday. She came in and sat down – she doesn't lie on the couch. She used to lie on the couch but now she prefers to sit. She appeared very anxious and said, "Why don't you speak to me?" I said, "What makes you think I am here to talk to you?"

B: You might say, "You seem to feel dissatisfied with the language that I do talk. You sound as if you felt that you wanted me to kiss you, to talk that language; but it seems to me that you are also very anxious that I should do nothing of the sort. You don't even take

the risk of lying on the couch in case I were to start using a language which you do not want me to talk." I don't think that it would in fact be a good thing to say this to her because I would like her to say a bit more so that I could get clearer what it is she is complaining about.

P: As she lives in another town she comes by car with a chauffeur, and another woman comes with her as companion. She said, "The woman who comes with me asked me if my husband had known you for a long time, and I said he had. She said it is good to know the person with whom one has analysis; it avoids problems. Then I began to wonder what she knows that makes her ask me these questions. I don't want to tell my husband what happened with the psychiatrist."

B: How old is the patient?

P: Thirty.

B: And the husband?

P: I don't know. They have two daughters.

B: How long have they been married?

P: Almost ten years. She says she doesn't want her husband to know the story because she doesn't want him to feel afraid, as she is, that everybody will get to know about it. "I don't want my husband to ask me who knows and who doesn't." She was crying when she said this.

B: My impression is that she doesn't want you to tell everybody what goes on in the consulting room – she wants it absolutely hidden. I wouldn't give an interpretation at the moment because I would like to have some more evidence. It is like watching a television picture which takes shape in front of your eyes, but you have come into the story in the middle. The patient was sitting in the chair facing you, and crying?

P: Yes.

B: Able to see you?

P: Yes. She continued crying and said, "My sister-in-law had a lover. My husband said that if that happened to him he would kill his wife, the lover, and then would commit suicide. Once he picked up a revolver only because a man spoke to me. Once you told me that perhaps my husband couldn't stand knowing these things and that perhaps this could destroy our life together."

B: It sounds as if the important thing here is the threat of violence; it becomes dangerous for her to have a conversation with

anybody who is not her husband. Even her conversation with him was at some stage with somebody who was not her husband – when they were not a married couple. That would mean that it was dangerous for her to look for a boy-friend. It is quite bad enough looking for one anyway – you never know what sort of potential husband or wife you might be talking to. The trouble about this whole business of finding a possible mate is that neither of the two people knows who the other one is – they don't usually know themselves either.

To get back to the middle of this story: an analyst, and sitting opposite in conditions of privacy a woman of thirty, anxious, weeping. Supposing we come into that room: how would we burst in on this scene? Carrying a revolver in our hands? From the point of view of this patient she can be feeling that someone might do just that. You could say something of this sort: "I think you can be feeling as if you were a little sister of mine and I were a little brother of yours; as if you and I were playing some game which caused a violent and hostile intervention by some kind of father or mother with a dangerous weapon." Would that be helpful or not? Let's try another one: "You are feeling as if you are a young girl who is carrying on some sort of game with me like kissing, and that a father comes in and is extremely angry." Which story is one to tell? Which interpretation? Freud said that it is not simply a matter of interpretations of words, but 'constructions'. This is where the analyst has to be an artist – he has to make constructions of what is going on.

P: When the patient said that I had once told her that her husband couldn't stand knowing a story like that, I asked her, "Did you hear me say this?" She said, "Yes. You told me that some people could stand it. And I think that my husband couldn't. Once I came home late after a session with the psychiatrist, and my husband asked, 'Wasn't your session only for an hour?'"

B: Is her husband ill?

P: According to her he is mentally ill.

B: Capable of violence?

P: She says so.

B: We all know that crimes of violence are often associated with sexual events, and this can indeed make psychoanalysis a dangerous occupation. It is obviously dangerous to ignore sexual elements in the patient – that would not be analysis. On the other hand, to take up these sexual elements is itself a sexual act because there are two

people, in private conditions, talking and using words like, 'breast' and 'penis'. The pair are in fact in danger of being attacked on the grounds of behaving in a sexual manner. So the analyst can either be criticized for not doing analysis, or attacked on the grounds of having sexual talks with a married woman. I mention this not as a matter of anxiety – we have to face these things whatever job we do – but to sharpen up the problem of what interpretation to give this patient.

P: I remembered that I had started her session five minutes early because the previous patient had been absent. It came to my mind because she had said on another occasion that sometimes the psychiatrist didn't stop a session after fifty minutes and continued without noting the time. This made her feel very guilty because she talked so much.

B: There are some patients who would always object if you were two minutes late. But they will also object if you are twenty seconds early. You almost need a computer to be right. This is why it is important to establish your own discipline and stick to it. Of course you can always take up the point with the patient: "You are feeling that I have started late (or early, or gone on too long). You are disturbed by the fact that I haven't kept exactly to the schedule." How did it go on after that?

P: I said, "Perhaps you are wondering why I saw you five minutes early." She replied, "I didn't notice anybody coming out of your consulting room. I asked my friend what time it was. I didn't notice you saw me five minutes early." I said, "I think you noticed something, otherwise you would not have asked your friend what time it was."

B: I think you can only say, "Well, you don't agree with my interpretation. I still think it is right, although it may be wrong. Perhaps we could leave it to see how it turns out."

P: One other point I would like to mention is this: she had said earlier, "I feel that what happened with the psychiatrist can't be undone."

B: One could say, "Knowing the facts which you know, and knowing what sort of person you are, you feel that a mistake cannot be corrected or modified." If it is simply a question of sticking from that day onwards to a mistake which has been made, then she can feel very frightened of making *any* mistakes, or even of the analyst

making mistakes. Under these circumstances it is hard to see how two ordinary human beings could possibly make a success of it.

M: Do you mean that the analyst should have the discipline to treat a fact that is felt by the patient to be a catastrophe, as something normal?

B: No. I think he simply has to have a discipline which he preserves inside his own consulting room. For example, you cannot stop a patient, if she chooses, from throwing her arms round you and kissing you. The only thing you can do is to be in a sufficiently disciplined frame of mind for the patient to have a chance of recognizing that she is having no respect for you, that she is treating you as an object on which to exercise her lips. If she feels entitled to do this, where is it going to end?

M: Would she be trying to frighten the analyst?

B: It is quite possible. He is, after all, supposed to be sensitive to what is happening. But the patient can behave in a manner which makes it very difficult for him to remain aware of the situation, open to these sensations and at the same time able to think clearly.

16 [2]

Presenter: This is material from the second session on the same day. She had a very tense expression, more anguished than sad. She said, "When I got here this morning for my first session I felt very distressed. I went to visit a friend who told me that she had had a sexual affair with a teacher and as a result was pregnant. She had told two other people about it and soon everybody in the town knew about it. Her husband knows about it too, but they are making a show of living happily together for everybody to see. It reminded me of what happened with that psychiatrist; I felt that what had happened to my friend had happened to me. I was so upset I could hardly disguise my feelings from my friend. What confuses me so much is the fact that when I went to the psychiatrist I didn't want any such thing to happen." The psychiatrist had told her that she should work it through with him. Sometimes he held her hand and said that it would help them to feel close and would also give her the feeling that she had a body. I told her that I thought she had difficulty in recognizing facts, and that therefore she felt as if she *was* her friend, living her friend's life.

Bion: Did you draw attention to what she was afraid you might do?

P: Yes. She said, "What I am afraid of is that you won't understand my feelings.' I asked her what her feelings were. She said, "I would like you to embrace me but that nothing should happen."

B: She may want to have a physical contact with you, but at the same time she is afraid that you would tell the whole town about it. She also feels that if you embraced her, then *she* would tell the whole town about it. So while she may want an analysis, she is afraid of its

being a situation of frustration, danger and publicity in which everybody knows what is supposed to be secret.

P: She *is* afraid that people in the town where she lives know about what happened between her and her psychiatrist.

B: And there is also the anxiety that *you* know what happened – especially when she is telling you. The problem is how to have an analysis and keep you correctly informed without at the same time telling tales about herself and you. It is felt to be very difficult indeed to have an analysis *and* a private life, especially if she tells tales about herself. On the other hand, if she doesn't say anything about herself, how is she going to get any analysis? This brings out the real difficulty: it is felt to be important that analysis should be private, and at the same time that somebody should be helpful, that there should be somebody to whom patients can talk about their troubles. I know from experience how difficult it is to bring home to analysts that they should keep things private; it is absolutely vital that they should be discreet. How are we to have supervisions, scientific meetings and so on, and at the same time have respect for the privacy of the patient?

P: I said, "You would like to be held in my arms and caressed like a baby, but you are afraid that I won't understand that you only want to be treated like a baby."

B: The time to want that was when she *was* a baby, not today when it is too late.

P: I had a feeling that something very important had happened to her during her first year of life, something connected with being abandoned. In fact her mother had left her with the grandmother and had stayed away for four months. When she came back the baby didn't want her.

B: These facts are important, but what is especially important is *this* which is taking place today. We often talk of past situations – it is quite useful – but the past is past and there is nothing any of us can do about it. What we *can* do something about is the present. So, what has happened that has made this patient talk like this to you *today*? She is no longer a baby.

P: I wondered if she knew that I was coming to Brasilia and felt abandoned.

B: She certainly doesn't want to be abandoned or forgotten, but on the other hand she doesn't want to be talked about either. And she

can feel that you don't want to be talked about, that you don't want the whole world to be told that you are seeing her. Will you tell other people that you have a hysterical patient who wants to kiss you? Or is she afraid that *she* will say that her analyst behaves like that? It is felt to be extremely difficult to find out anything about a sexual life. If you want help, then it is considered that you must be hysterical. If you want a private life, then it can be said that you are paranoid. This patient will have been familiar in childhood with the feeling that it is impossible to have a private life; there were always people to tell tales, and parents to listen and watch. Coming back to the present: she is looking for a civilized adult, a responsible person to whom she can talk about things that she has never before been able to express to anybody.

P: She continued, "It was only after that thing happened between me and the psychiatrist that I discovered that I didn't want it to happen. Perhaps something I did induced him to act in the way he did. I always felt I was an unprincipled person; I think he must have realized that. When I was a young girl I went into the cathedral in the town where we used to live. I looked at a statue of Our Lady; she had a wound on her breast. And I looked at the crucified Christ and I started imagining things." I asked her what things. She said, "You can well imagine what the things were." I said, "Do you suppose I can see into your mind?"

B: She might be quite glad to know what you have in mind – it is so much nicer to know what is in your mind than to tell anybody what is in hers.

P: She said, "I was imagining tearing away the clothes of Our Lady and sucking her breast."

B: What ought she to be thinking in a cathedral? What ought she to think in an analyst's consulting room? One way to answer that is to find out what the analyst allows. If she says you can imagine what she would feel, then she invites you to say what you imagine. If you give an interpretation, then she can find out if you are struck dead or what happens to you. But if you survive, then she might dare to say whatever she thinks. So it is felt to be very important not to be the first one to tell.

One might expect that a woman of thirty would have worked through all this in the course of finding boyfriends, or of finding a husband. But she seems to feel that she would never dare to take

the initiative, would never dare to say things – especially sexual things – to the analyst. If the analyst had a crucifix or an image of Our Lady in the room, then she would know what was or was not allowed. But even then she can be shocked at the way in which the Virgin Mary behaves.

P: One of her phantasies appeared in an association when she said that she could have been a prostitute.

B: Supposing the prostitute, the sexual person in herself, wants to be free, wants to be liberated. You might know this, and might or might not allow it. Suppose you say or do anything which suggests that you don't mind her being sexual; or suppose you behave in a way which suggests that you think the Virgin Mary is really a prostitute. Then there would be trouble. She is afraid that if you do say it, she will go away and say, "Look what a blasphemous person this analyst is." But on the other hand she can still feel that she is also a person of some integrity and honesty.

You might find a way into this problem by drawing her attention to the fact that there is an honest woman wanting to be free, but that she feels it is frightening to want to be honest. The difficulty is how to be honest, how to be God-fearing, how to be sexually mature, how to have children in the environment in which she lives. All these are felt to be problems which haven't been solved; some of them are felt to be problems which will never be solved until she tries them. But by the time she has kissed her psychiatrist it is too late. Before that, she doesn't know what she would feel; afterwards, the damage has been done.

No child can run the risk of asking questions about sex without being told, "What! Don't you know that?" Or, "However do you know about things like that?" This point also applies to religion: if a child goes into a church and sees a figure of the crucified Christ, it is felt to be very difficult to ask, "What is that?" It is difficult to learn *anything* because you dare not ask questions. If you do, you always know too much or not enough; you are ignorant, or you are religious, or you are an atheist. This woman of thirty has to come to an analyst and hopes that she can ask questions without getting into trouble. But of course one analyst is felt to be very much like any other, one small child very much like any other, one parent or grown-up very like all others. It is difficult to get the kind of mental food that makes the mind grow up.

17

Presenter: The patient is a man of thirty-four who has been in analysis for about a year. He was born into a very poor family in a small town outside São Paulo. When he was about twenty he went to the city; he had no money and was starving. He met a girl whom he married six years later. He says he didn't want to get married but did so because of social conventions. He complains of being unhappy and says he has had a stomach ache for about three years. He has a theory that this ache is due to his unhappy marriage. They have no children. During the past seven years he has become extremely wealthy but has not told his wife. A month ago he left home.

I would like to present one recent session. He arrived, said "Good morning", shook hands with me as he always does, and lay on the couch. He said, "This week I had no dreams. Today I was supposed to phone my wife at one o'clock but I didn't. I have no telephone so every day at lunch time I go to a friend's office. At ten past one my wife called me – I don't know how she discovered that I was there."

Bion: I am puzzled. He is describing a situation in which his wife doesn't know he has the use of a telephone. So that's all right – there is no mechanical communication. The next thing you hear is that *he* doesn't know how *she* guesses where he is. What apparatus is she using to find out where he is? I am not asking the question to suggest anything about an interpretation, but to draw attention to the fact that this seems an extraordinary story. He becomes very wealthy; his wife doesn't know anything about it. What is this apparatus which is being used by which he doesn't let anybody know his whereabouts or whether he is rich or poor, and this same apparatus by which this is found out?

I would remain quiet about this, but I would like to know what is the clue to this system of communication which is also non-communication – but which seems to work.

P: He continued, "I went to the bank to talk to a girl who works there. I noticed she had been sunbathing, so I asked her, 'Do you go sunbathing every week?' And she said, 'Yes, every week.' I asked her if she was going to do so this week-end, and she said she was. I asked her where she sunbathed. She said at home. I asked her if she had a swimming pool at home and she said, 'Oh, no. I live in a flat, but the sun shines in the whole day.' I suppose she doesn't know I'm a millionaire and that I have a swimming pool. Then I told her that I was betting in the sports lottery in order to get rich. She said, 'If I won in the lottery I would try to see the whole world.' I said, 'Oh, the rest of the world is the same as it is here. It isn't worth while being rich because then we get preoccupied with not growing old and not dying.' She said, 'Oh yes, Onassis would know all about that." Then he said, "I think I am getting a cold again. I'm convinced that my illness has nothing to do with my wife. She is not guilty. I am trying a test: I'll stay at home until the end of the year; if my illness isn't cured by then I will definitely leave." I asked him, "Why do you think you have a chance of being cured?" He said, "I don't know. But I do know that my wife isn't guilty, and besides that, I can try Positive Thinking." This is a kind of church run by a Japanese.

B: I find myself wondering about his visit to the bank. People usually go there for financial reasons, but *he* had a most interesting conversation – which is not what is ordinarily arranged by a bank. He is apparently sure that it is only one-way traffic: the girl who goes to the bank, theoretically to make a living, couldn't possibly know anything about finance or about who has any money. I can see that employees of a bank might know very little about the bank's business, but on the other hand I should be extremely surprised if they don't occasionally talk together about the clients who come to the bank. Why does he suppose that whatever he uses to investigate the girl – whether she is available at weekends for example – couldn't equally well be used by the girl to investigate a possible boy-friend? Does he believe that analysts never meet, that they couldn't have a sort of central bank of information about patients? I am not particularly interested in the answers to these questions, but I *am* interested to know what this one-way system is that he relies on.

M: He was hiding his wealth again – the situation at home was repeated in the bank.

B: It gives some idea of the use to which he puts his home, the use he makes of his office, the use he makes of the bank. One wonders why he is coming for analysis.

M: Perhaps he wants to know how his system functions in analysis.

P: I have formed the opinion that he is emotionally very poor.

B: Yes, right. How would you make that clear to him? Theoretically you give an interpretation, but of course when you do that there has to be a receiving end to it. So there is the problem of what he would hear you say. Could you go a bit further in expanding this idea of his being emotionally poor?

P: He wears bad clothes, he can't eat without having an ache, he doesn't know how to use his money.

B: That doesn't surprise me because money is only valuable as something which is usually exchangeable for something else. But if he doesn't know what to do with the money, it hasn't any value. Let us go on with the material now.

P: He says that he knows his wife is not guilty because after he left home his pains persisted.

B: This makes it seem as if he was afraid that she was trying to poison him. It might be anything from physically poisoning his food, to some other kind of poison. This is an illuminating comment of his. What concerns us is what he thought she was guilty of.

P: I said to him, "Does this make any difference to your difficulty in living together with a woman, sharing your inner feelings, trusting her?"

B: It might perhaps be wiser to say, "You don't seem to feel that you could trust anybody – or at any rate, any woman. Although you seem to have relationships with these creatures we call women – a wife, a bank employee – I think you are very suspicious of them." The next point is more controversial: I would like to say, "I think you are also very suspicious that you have a sort of woman inside you. When you talk about a stomach ache, you are really talking about a bad thing inside, and you are frightened of it. Sometimes it is as if it were outside you, like your wife or the girl in the bank. I think you feel that *I* am really a dangerous woman whether I am outside you or inside you." I am hesitant about that because he may not have got far

enough to understand such an interpretation. I haven't the slightest doubt that he would reject it, but that doesn't necessarily mean that he wouldn't be able to understand it. However, I am simply talking about my impression and what I feel I would be *inclined* to say to the patient. Although this interpretation is probably correct, in practice there is this difficult question of whether it is the right moment to give it.

P: He said, "I think I'm going to change. My new house where I am living alone has a fault in the water system and I have to replace it. I have another flat that is not ready yet, so I think I shall return home to my wife. Besides that, living alone is beginning to interfere with my business." I asked, "Why is that?" He answered, "Well, I need someone to take care of my clothes and to prepare my food."

B: All this seems to me to be making excuses, giving explanations which cover rather than illuminate why he goes back to his wife. It might be more productive to say, "You seem to feel as afraid of this home to which you are returning as you felt about it when you left. Indeed I think that you fear that if you go on talking to me it will be like getting back to the state of mind which you have forgotten, getting back to what we call your 'unconscious'. And you feel much the same thing about the woman's inside, your own inside, and mine." He is afraid that he would never escape from it.

P: I said, "Since you have no financial problems you could employ a laundress, or a cook, or a maid. I don't think you realize that in returning home and setting a fixed period in which to get cured, you are playing with other people's feelings." He said, "You are clearly saying that I shouldn't return home."

B: I think the objection to your interpretation is that it had a certain moral quality. It is important to avoid appearing to be either his conscience, advisor, parent, or authority of any sort because he would be anxious for you to take over these functions. If he really feels he is cooperating with you, then he is returning to a frame of mind which might be appropriate to his being a child. But a state of mind suitable to being a child is not much good to the grown man. So there is a fear that he is getting back into a state of mind in which he is dependent on a woman – originally presumably the mother. Of course the final version of that would be going right back into the woman's inside, into the womb itself; there would be fear of having anything in the nature of genital intercourse with a woman either

because of the point you mentioned – his mental poverty – or on account of his physical equipment, the danger of going back into the woman's inside penis first.

It occurs to me that there is a feeling that he started his trouble by deserting his mother. But the next 'mother', that is the father, is also a source of anxiety. So there is the impulse to go back to the mother again. I think it is also related to the feeling of having robbed the mother of something if he leaves her, and of using the father's penis with which to get back into the mother. Potentially he has both parents against him – the deserted mother and the robbed father.

The internal object – the thing he calls a stomach ache – is in fact a frightening conscience. Indeed he fears the analyst as a reincarnation of the 'ghost' of the mother. One could say, "When you talk about going to the bank, what you are really meaning is going back to the mother's insides; but in the mother's insides you find still another mother, and you are afraid that these mothers have more and more mothers inside them." It depends on whether the patient can understand that. Here we can discuss any interpretation whatever; in the consulting room we can't. There is only one person with whom to discuss it, namely the analysand – and that is not supervision. There is always pressure to give the right interpretation – even when we don't know what it is. But the right interpretation must be within reach of the patient's comprehension.

M: It seems to me that he had made some progress when he said, "I know that my wife is not guilty."

B: I am not sure about that. It is difficult to say what constitutes progress. I think this is the nearest he has come to admitting a paranoid anxiety. From our point of view it certainly is a sign of progress if the patient is able to say something so clearly that we can at least try to interpret it. We can always argue that this is a sign of analytic progress: we hope that 'analytic progress' is the same thing as 'progress', but we don't know. I wish somebody would draw up a map of the human mind showing various directions analogous to north, south, east and west, but marked 'progress', 'regression', and so forth. You could mark the different kinds, like different instruments on an orchestral score – infantile, adult, or adolescent. So according to which one of those aspects of the score you were talking about, you could mark whether that was progress or not. The total picture would be one in which there would be arrows showing progress in one

direction, and progress in the opposite direction elsewhere – minus progress.

P: When I said, "If your problem is a place to sleep, a laundry woman and a cook, you can get all that with money", he replied, "But I feel lonely." I said, "I think that too could be managed with money."

B: Why did you say that?

P: Because I felt that he wanted an object to serve him.

B: I think it would be served with money if it were simply a question of *looking like* having company. But that doesn't solve the problem he has confessed to, namely of being alone. Would it be possible to draw his attention to the fact that he isn't quite alone because he always has his stomach ache? In a sense the loneliness is the desert which he feels he has created with his greed. Whatever it was that has been eaten up and destroyed leaving nothing, has turned into a bad stomach ache. If that is true, it suggests that it is extremely primitive, probably going back to the earliest meals of all. He may even have a kind of reminiscence of being so greedy that he finished up with having a stomach ache. The thing he has eaten has travelled right down to wherever his stomach ache is, and there it is felt to be operating as a kind of conscience. This loneliness is sure to crop up more than once. That seems to me to be progress – a confession that he has been able to get everything except love or affection; even in a crowd he is lonely.

He talked about the girl in the bank having mentioned Onassis. Did he say anything about what Onassis means to him?

P: The day after Onassis died, he told me this: "I read about Onassis' fortune in the newspaper. I calculated that his fortune was three hundred times greater than mine." For the last two weeks he has been very preoccupied with getting old – a rich man who gets old and dies. This is something new.

B: What is Onassis' wealth? Three hundred times as much as the patient's bank account? Or the fact that Onassis is dead? This is a matter of importance if the patient is expressing suicidal despair. In spite of these movements from one place to another, I think he can be afraid that the best fortune of all would be to be dead.

P: When I said he could use his money to get company, he said, "Oh yes, a female companion. I think it's possible that I don't really want to go back home because I never take my suitcase out of the car." This was a reference to the fact that he went to the flat three times to

return to his wife, but left his suitcase in the car each time. He said, "Just now when I was running down the street I saw a couple. He looked about forty-five and she was a very pretty slim girl of about twenty-three. At first sight I felt envious; I would have liked to be in that man's place. But then I began to think about death and old age. I must give up running after women – it is really absurd – there is something ridiculous about it that doesn't satisfy me." I said, "I get the impression that what frightens you so much is the idea of having a sincere relationship with a woman in whom you could put your trust." He said, "I don't think I would ever tell a woman my business. It wouldn't be worthwhile and would complicate things." I said, "I don't think you are aware to what extent you are suffocated by money. It is as if you were in a room, filling it with coins." He said, "I feel I must take advantage of my good fortune because I can now earn in one day more than I used to be able to earn in one year. At the end of this year I shall make a large profit and then I shall feel calmer." I said, "It seems to me that you feel you have to earn money endlessly. What will be the result of that?" He said, "Then I shall be safer." I asked, "In what way?" He said, "Nothing will trap me – not war, no crises, nothing."

B: If that were true, what is his problem? He has already spoken about his fear of the attractive girl. He seems to feel that there is no danger at all that he would ever be so foolish as to tell a mere woman that he is a rich man; he knows that the real danger is that he might easily appear to be an attractive prize for somebody, either because he has money or because he is capable of making money. He feels that there is no shortage of people who would want to marry him. His difficulty is how to combine this situation with the feeling that he needs a companion.

It seems as if his little excursion away from the womb leads him back to his wife who, according to him, is a most unsatisfactory mate. What is he daring to expose to you in analysis? You mentioned his emotional poverty, but he can be afraid of being emotionally rich as well. Whether it is his poverty or his riches, neither problem has been solved. If he shows his emotional potential, his emotional wealth, his gifts, he feels that everybody will want them. Therefore he wears appropriately shabby clothes and an appropriately mean state of mind, so that there can be no worthwhile motive for anybody to want to get hold of him. It can be said that if a man is poor enough in every

way, it is understandable that he will have a problem because nobody will love him. But this seems to be a rather different problem: that of the person who is not poverty-stricken, and of how he is to find a mate who would actually love him. The fundamental point here is that the person who lives alone in the desert is sure to be greedily impelled to satisfaction, greedily impelled to get some substitute for love or affection. This would apply to either of the potential pair: how is the potentially wealthy man to find an appropriate wife, or the potentially appropriate woman to find an appropriate husband?

M: Patients frequently tell us they want to be loved not because they are rich or good, but because they have faults and are bad. They feel there is no advantage in being loved for their good characteristics.

B: Who is likely to want to fall in love with bad people? On the other hand, if the person in question has everything, why on earth should he want to marry? Can psychoanalysis find some kind of solution to this profound problem of why the human unit is a couple? This teasing question runs through the whole of philosophical history; analysis is only a relatively recent approach to it.

This is the problem the patient is presenting to you: how are two people to come together in a way which is an adequate solution both of the wealth of each of them, and of the poverty of each of them? To put all that simply and primitively: how are the penis and the female genital ever to get together? People behave all the time as if it were the simplest thing on earth; there is hardly a boy or a girl who isn't convinced that they know all about it – or at least they think it's a good thing to pretend they do. It is over-simplifying things to say it is a 'sexual' problem. We need to consider the possibility that there is something which is not so simple as that; it might be useful to call it 'passionate love' – you have to find your own way of describing something which goes on extending long after adolescence. In certain rare cases a person is not satisfied with making money or having sexual intercourse, and hopes that there is somebody – perhaps a psychoanalyst – who will know the answer. I am sure there is an answer that nobody has yet found, so it is quite an adventure in which we are involved.

18

Presenter: When this patient, a man of fifty, comes into the room he has a ritual way of doing it. He takes off his coat and hangs it on the chair.

Bion: How long has he been seeing you?

P: Less than a month.

B: Did you know anything about him before he came to you?

P: No.

B: So he is really a stranger.

P: Yes. When giving his reasons for coming to analysis, he said, "There is a part of my character that I must tell you about. When I am away from home I am happy and I like to joke with people, but when I get home I change. I lose my authority, I complain to my wife about everything; if something is moved from the place where I put it, I get angry. I blame myself because my wife is a nice person."

B: He seems to feel that he can express these various unlikeable qualities to an analyst. So both at home and in the consulting room he tends to behave in a way which is not typical of the way he behaves in the street or in public. One could say, "Well, what of it? It's a usual sort of story" – except for one very important point. Why is he mentioning it? Why is a man of fifty bothered by it? And why is he coming to see you? That is unusual.

There is no reason to suppose that, if this story of his is true, he will behave any differently in the consulting room with the analyst from the way he would behave with anybody else. Of course his description of his behaviour may not be accurate. But I don't think I would ask him; I would assume that what I could see and hear for myself in the consulting room would almost certainly either bear out this summary he has given, or he would have to alter his views

about that summary. If he says his behaviour with you is different, you could say, "Why do you reserve this special behaviour for me?" But I would rather leave the matter alone; I would rather have the evidence of my own senses.

P: He said that he had the feeling that he was beginning to control himself, even at home; he was being less aggressive with his wife. I said that he was talking about this change in himself since starting analysis as if I was supposed to expect it. He said, "Yes, the last session was very useful because it showed me my egoistic side which I was not aware of. Before I started analysis I was always in a hurry: when the time came to stop work at the office I left in a hurry; when it was time to go to work I left home in a hurry. Now I'm not in such a hurry. And I can sleep without taking pills, although I have to leave them on the bedside table." I said, "Perhaps you are talking about capacities that you have been unable to use before – to sleep without drugs and to be able to think about them."

B: What strikes me is that although all his statements seem to refer to fairly blameless activities, he is speaking of them with hostility and with a certain degree of alarm. What is he complaining about? It is hardly likely to be any of the things he has mentioned. And yet he is probably complaining about something which is available for scrutiny in the consulting room.

M: I have the feeling that he is talking about something he hasn't experienced, as if he were a journalist who writes about the facts but hasn't lived them in reality. So he speaks about himself as if he were in the theatre, looking at something but not living it.

B: All right. What is this spectacle? I think it is one of these times when precise interpretations don't really meet the situation. Perhaps one would need to give an even more vague interpretation than the statements he is making.

P: I feel that he complains about things as if he knows there is a right way of doing them. So perhaps it would be useful to ask him how he thinks these things should be done.

B: The activity which is prominent could be summarized as a sort of ritual – coming to see the analyst, putting the coat in the right place – which is usually directed towards controlling an internal event. I don't think this point is part of psychoanalytic doctrine, but you may find it illuminating to make this kind of division – privately anyway. The contrast to it would be ceremonial which is over

and again intended to control some external event. There's nothing hard and fast about it, but one could say that military ceremonials are devoted to controlling some external source; private rituals are nearly always directed towards an internal condition. In this instance I would say that the patient is objecting to change. I would go further and suggest that he is not so much objecting to changes in the environment, as to changes which he feels are occurring within himself and which are out of control unless he employs some sort of ritual. He hates *any* change in himself and therefore feels it is important to preserve the status quo, to run the home as it has always – apparently in his experience – been run.

P: One of the things he complained about was that he felt he was behaving like the widening circles seen in water when we throw in a stone – but in an inverse way, as if he were going from the outside in.

B: I think the change in him is related in his mind to a deterioration, to a state in which there is not an expanding universe, but a contracting one. You could say, "You have given me a number of instances which all have one characteristic: you seem to object to the fact that there is evidence of change in you." If you think he can understand that, you can leave it at that point and see what his reaction is.

There is another interpretation which is of consequence: if he cooperates, he feels that his state of mind is nearer to that of a small boy; at the same time he can feel that he is mourning for his lost youth. Next I would want to point out to him that even if he were nought or five years old he could be mourning for his lost youth and fearing both his inability to do what other people can do – probably the parents – *and* his dissatisfaction with what he has been able to do so far. The feelings of discontent have been there for a very long time, even from the beginning of his life, and are still there today. Whether it be now at the latter part of his life, or then at the beginning of his life, there is an objection to change.

I wouldn't want to say that until he had had a chance of expressing a great deal more because it very easily turns into reassurance; it is like introducing a cure before he has been able to express his anxiety. I strongly suspect that he has never really been able to express his feelings of despair, depression, inadequacy and dissatisfaction. People dismiss a small child's depression as if it were of no consequence. That doesn't give the child a chance to have a real, good depression

which does no harm, particularly at times when it is appropriate. But people of fifty years old are liable to resort to drastic methods of expressing dissatisfaction, depression and resentment. There is a danger that this patient might take the law into his own hands and proceed to deal with the situation in a very unsatisfactory and inadequate manner. After all, there is something most unsatisfactory about a man of fifty who goes about behaving as if he were the 'life and soul of the party'. It is still more unsatisfactory if he gets fed up with the whole lot, and murders himself. These pills he keeps by his bedside are useful, but it does depend on who uses them and what for. I think he should be given plenty of time to have a thorough complaint about his inadequacy and resentment, including of course the hopelessness of analysis and analysts. Let him do all that, but don't let it obscure the fact that this is nothing new. As I say, he might have been mourning for his lost youth as a five-year-old or younger. We don't know what the drugs were then; there are plenty of things, like masturbation, which children are able to use as a method of overcoming feelings of depression or despair. The snag is that they work for the moment and then there is further depression and despair about the cure. So we should not be too precocious or too premature in giving an interpretation which the patient will use and regard as just one of these same old reassurances.

We always have to consider how we are to describe to the patient the situation he is telling us about. For example, why bother about his wife being ill-treated? The point that is of importance to the analyst is that the patient *is* bothering. When he is aware of the pressure to have and to love a home of his own and the inhabitants of that home, then it is important to draw his attention to the fact that he hasn't previously expressed so overtly his fear that he might be loving or affectionate or sympathetic – all of which are felt to be inferior, not at all grand states of mind.

19

Presenter: The patient is a twenty-seven-year-old married woman. I have been seeing her for six months. She has a great deal of difficulty in speaking during the sessions; she is silent for long periods. When she lies down on the couch she becomes very anxious.

Bion: Whose idea was it that she should lie on the couch?

P: She chose to do so. When she arrives she has a radiant expression and looks at me in a penetrating way with brilliant eyes; then she lies down. Every session since the beginning of the analysis has consisted of long periods of silence and signs of fear and anxiety; she described the fear as 'undefined' and cannot explain it. I would like to recount one of the most recent sessions in which I got the impression that she was more communicative. There was the usual long silence at the beginning of the session. Then, while she was still twisting her head, wringing her hands and pushing at the sleeves of her blouse, I asked her what was going on in her mind.

B: There are two people in the room, but the patient knows something that we can't know – that there is also a silence in the room. That silence isn't just nothing; therefore if she is afraid of the silence, she is not afraid of 'nothing'. The silence must be, as it were, the place where some person or thing is. I could put it like this: there are three people, three things present – the analyst, the patient and the silence. And it seems that the silence is the frightening one – at the moment.

P: The question I asked myself was, why is it so difficult for her to speak? Why does she think it is safer to keep quiet about what is going on in her mind rather than tell me?

B: If this object is silent, she would feel frightened of doing anything different from that.

P: After this long silence something very strange happened. I got the impression that there was an Egyptian mummy lying there and that there was a resistance in the relationship between us. I was surprised when the patient began to speak and said, "You talk about the things that I can't express. It is very difficult for me to talk at all, but harder still to think. When I try to think and can't, I feel very frightened and paralysed like a dead thing."

B: It becomes clearer that the dead mummy is very dangerous: if the dead mummy won't talk, then it is felt to be dangerous to be alive *and* to talk. If you listen to the silences as well as to what is said, then it becomes easier to understand what the silence is saying. If you talk, or she talks, it is impossible to hear the silence. Putting it in pictorial terms, it is a very lively ghost.

P: She said that when she managed to think and found the proper expression for it, she felt the tension ebbing away and was more relaxed.

B: The relaxation may be a nice experience, but it may not. One has to consider how she is lying on the couch; is she relaxed because she is on a couch? Is she more relaxed than the analyst who isn't on a couch?

P: At first it was very difficult for me to relate to the silence, and I couldn't listen to it with ease. But after a time I began to feel more comfortable when I thought about what was happening during the silence. I also caught myself thinking about things other than those happening in the session. The patient says she is very afraid that she won't last out the analysis.

B: It sounds as if she means until she is dead, as if she felt she had no right to a life.

P: When she said she couldn't speak I pointed out that she was in fact speaking.

B: I think you also need to point out that she has discovered that you can't speak if you don't know anything, if you aren't kept informed. So her silence makes you silent too: one of the two people in the room can't be an analyst, and the other can't be an analysand – neither of them can be satisfied. This object is a very hostile one; if she is not allowed to talk, then analysis is impossible. You might try drawing her attention to the fact that if she talks she is afraid of starting something; she is afraid of the opposite of the silence, afraid of talking so much that you cannot hear yourself think.

P: When I asked her what was going on in her mind and explained that I asked this because I couldn't go on working with no material, she replied that the only things she could remember were those from the past.

B: But she didn't mention them?

P: She mentioned that she remembered her father who was very severe and was always criticizing her. I asked her, "Do you feel that I am criticizing you?" She didn't answer.

B: I think there is great fear of the opposition and hostility of the dead father or dead mother to the person who goes on living. So it provides a sort of defence to say, "I may still be living, but it isn't a life worth living." What she seems to lose sight of is that if the analysis is not allowed to proceed, then there is no analysis. How did she come to believe that somebody or something would save her from that disastrous state?

P: She said she was afraid that I would send her away because she didn't say anything. I said that we should both try to forget that for the moment.

B: But should she forget it? Should she forget that the analyst might expect something?

P: I have tried to show her that collaboration is necessary.

B: The difficulty is how this is to be put to her. It isn't you who are stopping the analysis, going away. If there is no analysis, there is no analysis. In fact she is inviting you to say, "Oh no, I won't desert you." Then she will be able to show that you give her permission, as it were, to avoid having an analysis. But it leaves out the point that if you want to do analysis it is no good going on if you are not allowed to do it.

P: She was referred to me by her obstetrician because although she wanted babies she frequently miscarried. So she came for analytic treatment in the hope that it would help her overcome this problem.

B: Yes, but she is also wanting to be assured that if she gets pregnant she will have a good baby, or a good cure. But you haven't told her that a good analytic baby will be born. There can be a feeling that there is such a thing as a successful analysis, like a successful pregnancy, but what is born is another matter; she has to put up with the baby, whatever it is. It doesn't seem that she has ever worked out this point. I would be inclined to draw her attention to the fact that she feels able to come for analysis if she is sure that it has no effect.

In physical terms, if she is sure that she won't become pregnant she can do what she likes sexually. In the meantime she is not prepared to risk having a sexual conversation with you. But if sexual matters are never dealt with it is a strange sort of analysis. On the other hand, if it is the kind of analysis in which sexual things are talked about, there is also the fear that it will bring about some sort of pregnancy. Even rationally she can feel that if she changes in this respect her husband would be more prepared to have a relationship with her.

Almost anything you say to this patient is wrong; whatever you say gives the idea that she can go on behaving in that way and that you can still go on doing analysis. You are trapped into agreeing that she can come for the rest of her life even if there is no result at all. Analysis is practically the only contractual arrangement between two people in which you feel you can keep on for ever – or anyway for as long as you like – without anything ever happening. It is difficult to know what to do because you need to give an interpretation which isn't, as it were, an accusation.

P: Sometimes I feel like letting the silence continue to enable me to know what is going to happen.

B: It is worth trying. But there again you have to be careful. The analyst can be silent, can give the patient plenty of time, and yet it can be an expression of hostility. The patient must think that there is some reason for spending so much time and money; and we know that there is no advantage in having a useless analysis.

M: There may be masochistic impulses present – a form of punishment and guilt.

B: It is true that one suspects that there must be some pleasure or satisfaction obtained from it. For example, if as a child she refuses to pass motions or urine, that would be a very effective way of upsetting the mother. She can get pleasure out of thinking that you mind what happens to her; alternatively, she can get the satisfaction of feeling that you don't care. It can also be a sort of mental masturbation; she can get sexual gratification out of the feeling that she gets nothing out of the analysis.

20

Presenter: The patient is an eighteen-year-old who has been in analysis with me for two years. He had to wait for two months after the initial interview before I had a vacancy; he wouldn't consider going to another analyst. His father, a doctor, died a year ago.

He always arrives in a great hurry, looking scared and anxious, his hair uncombed, his clothes untidy. He complains of pains and says he has to fight with himself to come to the sessions.

He arrived late for the session I am reporting, saying that his car had run out of petrol. He was even more anxious than usual. He lay on the couch but couldn't speak. After a while he said, "I'm very frightened because I can see something but don't know how to describe it – I can't find the words. There are scenes, like a movie, passing so fast on the wall at the end of the couch that I can't connect with any word in time."

Bion: If you lay on that couch, what would you see on the wall?

P: Just a bare white wall.

B: He *can* see something. I think he can see your words going right over his head and hitting the wall.

P: He said he would like a special machine to collect his thoughts. Then I could translate the thoughts and understand what he was seeing.

B: He is reasonably sure that you, like most other people, cannot see anything on that wall.

P: He said he was able to control pain. I asked him what sort of pain. He said, "It is too complicated a process to explain to you. If my father were alive he would understand and explain because he was a very good man."

B: This statement that his father was a good man is intended

to be heard by the father. But this father is a dead father – and that is a different matter. The dead father is sure to be very angry, very hostile to the son who goes on living. And the situation would be made much worse if the son did anything which made his own life worth living. The dead father becomes a very bad, envious, hostile and lively ghost.

I don't think this is a matter of much importance at the moment; these feelings go back a long time before adolescence – they would certainly be the earliest feelings of all. In a somewhat technical way one could say that when the baby is born it kills off the father and takes possession of the mother's breast which is the father's property. Those feelings are ordinarily made more bearable if the father and mother are happily married and the atmosphere in the family is flatly contradictory to this frightful story. But suppose there are no reassuring father and mother visible – only a blank, white wall. It is possible to see *anything* on that wall, however terrifying and however intolerable. If there is a good, real father who is able to have a good, real loving relationship with the mother, then that wall will not be so blank.

This blank is brilliantly described by Milton in *Paradise Lost* where he talks about not having sight; he is surrounded by "ever-during dark". And "for the book of nature fair" he is presented with "a universal blank". This "universal blank" means 'nothing', but it also means 'white'.

Ordinarily we do not reassure patients; we do not tell them about our private lives or anything of that sort. So we do present them with a universal blank. "And wisdom at one entrance quite shut out", says Milton. If we obey the ordinary classical rules of psychoanalysis, we seem to be doing exactly what the patient is afraid of – giving him no good 'sight'.

P: He often complains that if he knew something about me and my life he would feel much calmer.

B: One can only assume that *so far* he feels that you are a friendly human being, not a horrifying and dangerous ghost. But I can see a difficulty: if you try to draw his attention to these terrifying ideas, then you are becoming a hostile person who tells him terrible and frightening things. I think he has enough sense of reality to feel that you are a very important person. In so far as he is able to 'push out' towards the analyst, he meets a different 'thing', something which is

'not him'. And so far he feels that it is something helpful, that you are a bit more good than bad. I don't know how much more; probably very, very little. I might try to say, "You think that if I told you I was a good father, you would find it easier to come here. As it is, we don't know how you have managed to get here again today."

P: He says he only comes to the sessions because he is unable to sleep at night when he is lonely and sees frightening things. He is very angry about having to come to analysis; when he does come he cannot tell me what he feels. When he understands something I tell him, he gets even angrier.

B: If he goes to sleep he is afraid he will never wake up again. That has already been described by Shakespeare in *Hamlet:* "but in that sleep of death what dreams may come?" So far he has probably been saved from killing himself because he is afraid that things would be even worse if he were dead amongst all these ghosts and horrible things which come when he is asleep. You give him a chance to believe that there might be one good person. He knows he wants to believe that, yet there is no reason to believe that you are any better than anybody else, no reason to believe that you are a good father or a good mother.

P: He quarrels with his mother at home. She often weeps and says she wants to kill herself because she cannot bear her loneliness. He tells her, "My analyst doesn't cry."

B: From a very early stage the baby can press out and get in contact with – we hope – a good breast, a good mother. But the father is a 'mother' who doesn't put the baby to his breast, so this is one of the first ways of telling a difference between a father and a mother. One could say that, in a sense, the father is a bad 'mother'; and the mother isn't really a good mother because she doesn't produce good milk from her eyes. A baby may not be in contact with the breast, but quite soon it can follow the mother about with its eyes. In this way it is possible to have a good relationship with the mother who isn't even in contact with the baby. But the mother this patient can see with his eyes, can take into himself with his eyes, doesn't produce milk but tears.

You could try saying something of this sort: "You are afraid that if you try to get good health from me, I shall not produce good milk but bad tears." The baby can feel that it wants or tries to get good milk;

or good analysis in the case of this patient. But what he produces isn't good milk – it is urine.

This patient has continued trying for two years to behave as if you are a good analyst. He is still alive, so it may be that he is right. You could say, "It doesn't prove it, but I think it is sure to be making you feel that I might be helpful – even though you are very frightened of my being extremely hostile."

21

Presenter: The patient is a thirty-nine-year-old woman who started analysis four years ago. She complained of feeling very strange; she didn't know who she was any more, she only knew that she was not herself and was afraid she would never come back again. She thought a 'head shrink' would be able to bring her back.

I am reporting a session that took place four months ago. She said she wanted to tell me something that happened the previous day. "We were on our way to a party but couldn't find the number of the house where it was to be held. I began to feel bad, as if I was going to disappear. I quickly got into the car and felt more secure. My husband backed the car and we found the right house. The moment I was under a roof I felt secure – it seems that the roof and walls give me a great feeling of security. In the living room I felt very well, but the moment my husband asked me if I was feeling well, remarking that generally I don't feel well in unfamiliar places, I started shaking and feeling bad. I was talking to some friends and looking at the food – I couldn't wait to start grabbing it."

Bion: She seems to be telling two different stories: one is about the feeling of security; the other is the answer to her husband. I don't know to whom the first one is the answer, but it is probably what she feels able to tell the analyst, and even to some extent herself. But the moment the analyst becomes somebody who wants to know, "Are you feeling well?" – like the husband – then the language she speaks is suddenly quite different. Why are there these two different stories? Is the one she tells her husband told in that particular language in order to make it easier for him to understand, or to make it more difficult? What she told her husband or anyone else is, in my opinion, of very little importance. What is important is what sort of language this

patient is likely to speak to the analyst. I would ask myself whether I would be able to do analysis if the patient speaks these two different languages to me.

It is quite likely that she describes these peculiar feelings if she thinks it safe to talk to a particular person. But she may be afraid of what will happen if the analyst turns into a sort of husband, the sort of person who could see her as often as a husband. She might speak what seemed to be fairly ordinary conversational language – unless she was going to continue seeing the analyst. In that case she is almost sure to speak this other language.

P: It is very difficult for me to understand with whom she is talking. I feel as if she is talking with herself.

B: That is an important point: people do talk to themselves. So even though the analyst is there, the patient may be talking to herself – and the analyst can hear that conversation. I think I would try to show her what seems to be going on while she is in the room with you. For example, I might say, "I don't think you are talking to me; I think you are behaving as if I weren't here." I would try to draw her attention to the fact that she seems to be busy making noises so that she can feel somebody is in the room with her. If a mother leaves her baby alone, it may start making noises, 'talking', to help it to believe that somebody else is in the room. Sometimes the baby makes angry noises in order to feel that if someone in the house is being angry, that at least proves it is not alone.

It seems clear, from what we have heard, that this patient is afraid that if she comes to the analyst often enough – and certainly if she is married and lives very close to a person who is not her – then the analyst or husband will be bound to find out all sorts of things about her. Some of them she wouldn't mind: it is usually felt to be quite respectable to be ill, to have these feelings she has when her husband asks her a question. But suppose she is at a party where there are a lot of nice things to eat and she proceeds to eat as many of those things as possible, that would not be respectable. Similarly she can feel that she has been well brought up, has a home, an income, a husband, and now she wants analysis as well. That also may not seem so respectable; it may seem to be very greedy. That is not a nice idea, either about herself or about the analyst who may equally be very comfortably off and yet be glad to have a particular patient as well.

The analytic situation is a dynamic one and the analyst has to be able to see that dynamic situation which is *always changing*. Consider even the little we have heard about this patient so far; you can see what an enormous number of stories can be worked out in a short space of time. What the analyst has to know is, which story at which time and, if possible, why. What leads this patient to be afraid that she might be accused, if the truth were known, of being very greedy? Another time she might be very afraid that the analyst will say, "You are so ill, you are trembling and shaking so much, that you will have to go into hospital." Indeed, in this respect the patient may feel that it is difficult to know what language to speak, or whether to make clear what she is talking about, because there is no knowing what the analyst, or even her husband, would do if he knew the truth.

It is this dynamic situation which is very badly served by trying to impose upon it a rigid system of psychoanalytic dogma or theory. There is no substitute for what patients and analysts can see and hear for themselves. For a patient to go by hearsay about any particular analyst is dangerous and contrary to *genuine* analytic theory or philosophy. Similarly it is dangerous for an analyst to try to substitute some dogmatic authority or person who has told them how the patient should be treated. That, you can be reasonably sure, is how *not* to treat the patient.

22

Presenter: When I started with this patient four and a half years ago, it was my first analytic case. I saw him five times a week for four years; since I came to live here I have been seeing him twice a day on two days a week. During the whole of the time I have been treating him I have been doubtful whether I would ever be able to become an analyst – he always made me feel very insignificant, and besides my own problems his behaviour confirmed my fears. I want to raise this question: why does this patient make me feel like that?

The motives that brought him to analysis were twofold: he was going to work as a publicity agent – he said he usually destroyed everything he most loved, and this agency was something he had always dreamt of doing all his life; and he had a bad relationship with women.

Bion: How did this patient come to you?

P: Through the Institute of Psychoanalysis.

B: We don't know what he had heard about analysis beforehand, but patients frequently feel that the analyst knows very little about it. You yourself may know that you don't know much about it – it would be very extraordinary if you ever thought that you did. If you ever think that you know much about analysis, you can be reasonably sure that you are deteriorating.

P: Then I am happy!

B: It is often helpful to go to the very thing which obtrudes: if you feel that the patient is able to make you feel guilty or frightened or anxious, that is what you need to investigate.

P: Should I cope with it in my own analysis, or with my patient?

B: There is no reason why you shouldn't take up the point with your own analyst, but I think it is a different matter with the patient.

Wanting to be analysed is a different state of mind from analysing somebody else. The two states may look the same, and if somebody was able to record it, it would sound the same, but they aren't.

There are many people who regard doctors and surgeons as inferior creatures. After all, it is a situation which has a long history; in England barbers were the earliest form of surgeon. You must always be ready to find that patients secretly think they are socially superior to you. There are many different varieties of this; it is only in the analysis that you have a chance of becoming interested in *how* patients manage to make you feel inferior. One could say that surgeons and doctors are relatively respectable; but who are psychoanalysts? Nothing at all. They are the most inferior of all.

P: The patient appears to value psychoanalysts highly: his wife is a psychologist and she is training to be a psychoanalyst; in his publicity agency he uses advertising with a psychological background, and he is very successful with it. Nevertheless none of this appears in the analysis.

B: For whom is he being a publicity agent in the analysis?

P: I don't seem to fulfil any useful function for him. He never gets into real contact with me; he only talks about his publicity agency and how wonderful it is, how well it works. He has a sister who is psychotic and is regularly committed to mental hospitals – she has recently been committed again. At these times he finds I can be helpful – I acquire some function.

B: He can be anxious that you will not be interested in him unless he is a serious case, unless you could say that you have cured a psychotic patient. He can be afraid that you want to use him to show what a good analyst you are. I think this changes all the time: sometimes it will be you wanting to be publicized; sometimes it will be his wife; sometimes it will be himself.

P: Before I moved here I noticed that although he never missed a session he was very punctual in his unpunctuality – he was always twenty minutes late. I tried every way to analyse this but he continued to come twenty minutes late. But since I started a different schedule here he has never been late. At the same time he went into a depression – for the first time.

B: Who does he pay?

P: He pays me directly.

B: Does he pay a reduced fee?

P: He did at first, and I have made adjustments in line with the rate of inflation. Nevertheless he still pays less than any of my other patients. I like him very much; I don't know whether this disturbs the relationship.

M: Perhaps he doesn't feel entitled to use the whole session because he pays a low fee.

B: I think that is right. It is one way of paying for the session: "I may not pay the full fee, but then I don't have a full session, so it's all right." I think he feels guilty about this.

P: He was breast-fed until he was five years old, not because the mother had enough milk for him alone, but because the two sisters born after him were not breast-fed – the first died and the second is the psychotic I mentioned before. There is a third sister, the youngest, who was breast-fed.

B: The other members of the family are not getting any analysis, so he is the only one who is favoured. I think he can be afraid of what he will have to pay for this favoured treatment. There are two possibilities: one is to be a good publicity agent for you; the other is to knock off twenty minutes from the session or get depressed. But there is another possibility; he might have to go into a mental hospital like his sister.

P: He is the only successful member of the family. He enjoys the situation but feels uncomfortable about it, so he doesn't enter into any close personal relationships with members of his family. He has an enormous number of friends and is always together with groups of them.

B: It seems to me that there is anxiety here about being the favoured patient and the greediest patient who takes everybody's fees, everybody's analysis. So he gets the analysis – the good breast feeding – which the other siblings do not.

P: He is the first patient in the morning – the first to be fed!

M: Superficially he gives things to others through the publicity agency, but he doesn't actually give anything to the family.

B: Yes, there is a great deal of greed and meanness about it.

M: One of his reasons for coming to analysis was the fact that he had difficulties in relationships with women. I see a parallel between this and his relationship with the analyst.

B: I think that when he says he can't have a relationship with women, it isn't really true; the real truth is that he cannot relate to

anybody. It sounds more plausible to say his difficulty is with women. A patient who says he is a homosexual isn't fond of men – he hates them. The real difficulty with a patient of that kind is that he hates people.

Anybody can be married – there is no difficulty about that. Then he can say to the whole world, like a publicity agent, "Look! I'm married; I'm just like a normal man; I'm just like a father who loves his wife and children. Look at my family!" I certainly think he wants the analyst to fall in with that and help show what a good man and husband and father he is.

P: I feel that his relationship with himself is a publicized one, not internalized. Therefore he can't have relationships with other people.

B: Yes. He doesn't mind about his wife, children, psychotic sister; what he minds about is that they can be used for purposes of showing what a good man he is. In other words, the wife and children are not loved – they are simply used for purposes of loving himself.

P: At the beginning of the analysis he had a serious problem with hypertension which improved later although it had not responded to medical attention. I discovered later that he was taking appetite depressant pills as a stimulant.

B: I think that he feels he has a very hostile object inside him which he covers up with all this publicity and family affairs in order that he cannot look inside himself and see what this very bad thing is which he calls 'hypertension'.

M: Would the adipose tissue be a way of holding on to the bad object?

B: It could be. In the meantime he attacks this bad thing inside him: he throws amphetamines at it, he throws food down his gullet so as to hit it, to kill it; he tries to starve it out of existence. Whatever he does, this bad thing which is felt to be a bad part of himself might just as well be somebody else because he has no control over it. He is only a sort of publicity agent: it is his business to look nice, to act as a disguise or cover for this bad thing inside him which is greedy, violent and hostile.

P: He says he is better. I notice that he is thinner.

B: That is what his *physical* appearance tells you. But that is on the outside – like this adiposity. His fear is of what you might tell him; indeed, there is always the risk of what an intuitive wife, son or daughter might tell him. Coming for analysis, or even having a

family, is taking a great risk – the risk of being found out. I would be extremely suspicious about the nature of the improvement, of its always being a part of the publicity, of his wishing to get you to agree with it.

23

Presenter: The patient is a man of thirty, a child psychotherapist. When he came to me he had had four years of previous analysis. At the age of fifteen he had experienced a religious crisis. At that time he had eight months' psychotherapy with a Jungian priest. He is the oldest of six children – four boys and two girls. When he was eleven he seduced his nine-year-old sister; he appears to link that experience with one of a homosexual nature with a cousin of seventeen when he was fourteen, and a second experience with an employee of his father's, aged twenty. During his medical training he had a three-year homosexual relationship which ended violently. He chooses handsome men of good education, and psychiatrists like himself, with whom to have homosexual relationships. Apparently these relationships consist of oral and physical contact, but are without orgasm. It is not clear whether he has engaged in fellatio. The partner has to be young and married; he tries to seduce the young husband by behaving in an intellectual way.

In every session he says, "I had a dream."

Bion: Whose idea was it that he should tell you these dreams?

P: He is psychoanalytically oriented; he makes interpretations and wants to control me.

B: Such a patient as this thinks he knows what the analyst would like, and since analysts like dreams he will give the analyst dreams. It is one thing to be told dreams if that is the quickest and easiest way in which the patient can talk to the analyst – dreams are very useful if there is nothing better – but does he tell you these dreams because it is such a useful way of informing you of something you cannot know, or does he tell them because he thinks you would like to be

told dreams? What is his motive? Is he mentioning them in order to seduce you, or because it is the best way of talking?

P: He has difficulty in relating to me – except homosexually. It seems that the dreams are used to communicate something he cannot contain because when material comes into the session that he cannot contain he weeps.

B: One of the striking things about this is that he is in fact very frightened of sex; he is frightened that you might have some sexual relationship with him, and he is frightened therefore of having any relationship with you, whether you are a man or a woman.

P: This is one of the dreams he told me: "I was with a group of people who were soccer players. I was a press reporter and found myself with Pele. He was in front of me and I crouched down close to him and had oral sex with him. I fought against the relationship. I had an ejaculation in the dream. When I woke up I remembered that my little brother had a great admiration for Pele." His brother, whom he admired very much, was a good soccer player but the patient was never able to emulate him. On the other hand, he had a poor opinion of his father who had been an immigrant, worked as a pastry cook, and was alcoholic. The patient suffered greatly during boyhood because he was never sure who would take care of him. They had no money to pay the rent or buy food; they had to ask for help from the mother's family. My interpretation of the dream was that he was trying to establish the same relationship with me that he had with Pele, trying to absorb something valuable from me. He assumes the role of the wife of the one he loves.

B: I think the trouble is that as soon as he wants the feminine role, he becomes afraid of it and wants the masculine role; when he has the masculine role, he is afraid of that and wants the feminine role – and so it goes on. In short, he wants some assistance from you but doesn't know how to get it; he is afraid of you, whatever you are. In so far as you are the mother, there is the fear of needing to have a relationship with you, or you as the mother's breast. But then he is anxious about the intercourse in which the breast would penetrate his mouth. As the baby he is anxious to be able to walk; he wants to get about by himself; he would like to have feet like Pele because then he could be a wonderful athlete, but it's no good – he can't be Pele the Athlete.

There is yet another difficulty: in so far as he *wants* to do what his mother wishes, he also has to *do* something. One of the earliest things he has to do is to evacuate his bowels. That is made easier if he finds he gets sexual pleasure out of passing faeces through his anus so that he has a sexual feeling with this black object which is inside him. For a while that solves the problem of the sexual relationship which is partly with his mother who wants him to evacuate his bowels, but partly with this bad thing inside him of which he is frightened. So this is another failure.

In the next phase he tries to have a sexual relationship with his sister; he tries to be just like the father and mother. There's nothing particularly dangerous about having sexual relationships with a sister. Why it is discouraged and why it is not thought to be 'normal' is because children who try to do that are sure to fail, and the form that the failure takes is that they find there is no pleasure in it. All they learn is that they can't have sexual intercourse, and that since there is no pleasure in it there is nothing to look forward to. The boy also probably learns that something frightening has happened to the girl's penis. So the lesson that is learnt from this premature sexual marriage is learnt at an impressionable age and is very difficult to unlearn. As a result the boy doesn't want to see the girl's genital if he can help it – it is too frightening, it is not pleasurable, it is not sexually exciting, there is no advantage in having such a relationship. So he is as far away as ever from a happy sexual life.

P: I forgot to mention earlier that he despises women because they don't have penises.

B: He can also despise himself because he has no breasts. Next, he tries a brother. (I don't think it's one after the other at all; all these things probably happen in any order.)

P: He used to sleep with his brother. Because he suffered from enuresis he had to wear a diaper in order not to wet his brother, and although he was older than his brother, his brother had to help him change his clothes.

B: The relationship with the brother is also awkward. If he tries to feed from the brother by taking the penis into his mouth, he doesn't get good milk out of it; if he tries to feed his brother he can't feed him with good milk – only urine.

So: the mother is no good; emptying his bowels is no good; trying to walk is no good; trying to have a sexual relationship with a

sister is no good; trying to have a sexual relationship with a brother is no good; trying to feed a brother is no good; trying to be fed at the penis is no good. They are *all* failures, one after another. By the time this boy enters the latency period everything is a failure, everything without exception. He has no feelings at all, or if he has any feelings they are depressed.

Then he goes to see a psychoanalyst. What is the good of that? Everything has always failed and the analyst only talks. So he tries another psychoanalyst. What happens then? Another failure – he knows it is bound to be no good. So he goes to a third analyst. But more and more analysts are not going to be any better – they are all as bad as each other; they just talk. How is a patient like this possibly to believe that verbal intercourse could be the slightest use? One could say that he would have to be stupid or in a very bad way to believe that it is any good at all. In other words, he has learnt, thoroughly learnt, at a very impressionable age, that *any* relationship is no good. It is no good at the breast – something has gone wrong; it's no good at the other end of the alimentary canal – the anus is no good either; it's no good with a sister; it's no good with a brother; it's no good with a penis; it's no good with a vagina; it's no good with the mouth. There is only one thing which stands between him and death, and that is analysis. Suppose there is some truth in this idea about dreams – this would make it slightly hopeful. If he talks about dreams, perhaps you will say or do something that will save him. It is such a very faint hope that it is almost like fooling himself. All you have to go on is these dreams; and all *he* can believe in is the hope that it isn't all nonsense.

You are dealing with a very dangerous situation; at any time this patient may simply be overwhelmed by despair or resentment or hatred, and kill himself. Although he may not know how dangerous the situation is, you do – so much so that you can almost be afraid of giving an interpretation.

P: I do have great difficulty in giving him interpretations.

B: Yes, there is such a mass of things to deal with that it is hard to know which one to choose. I think my inclination would be to try to bring out into the open the fact that he does not believe in psychoanalysis or in you, because he thinks it very unlikely that he will be cured or helped in any way. Indeed, how did he manage to come at all? I would try to uncover this fundamental hopelessness and

despair for one thing, but underneath that, his hatred and resentment of this hopeless situation. There is always the fear that he will either do nothing at all, or break out and murder somebody – and the one person who is always available is himself.

The central problem is: how can you find a chance of drawing his attention to the fact that it is very difficult for him to come to you without believing that he is fooling himself or fooling you? In other words, he is feeling that he has to depend on a lie.

P: In order to deny the depth of his distress he said, "I am lying to you." He wept, then said of his homosexuality, "I can't explain it; it is a compulsion. I can't keep it inside myself." When he leaves his sessions he goes to look for a partner.

B: I think I would say to him, "It is true, what you say, but I think it feels as if this bad sexual partner which you call 'homosexual', but which really means bad sex, is something inside which you feel is you, but it might just as well be somebody else." This bad thing inside is felt to be determined to have a sexual life, so it uses him, his mouth, his penis, his anus, in order to do so. And he has to have an intercourse with whatever this thing inside him insists on – anything; it doesn't mind what. But he feels that this same object has forced him to come to analysis whether he wants it or not. So he is frightened by a situation in which all of him is false: he doesn't want an analysis; he doesn't want sexual intercourse; he doesn't want *any* intercourse, not even a conversational one. But this thing inside him is determined to burst out and have an intercourse, using him to have it with.

24

Presenter: I would like to raise a point about a patient who has been in treatment with me for a year: whenever she makes any progress she becomes quarrelsome. This session took place last Monday. She arrived very happily saying, as she came into the room, "Now you must explain to me why I was so happy after Friday's session, and why I am happy now." In fact the Friday session had not been a happy one; she had mentioned suicide and the fear that she was going to die of a heart attack. She said, "I don't understand what you say to me; you don't even talk to me. However did I manage to get better?" She lay down on the couch and said, "You don't need to be so nervous and so tense. Why are you making noises with your fingers?" I pointed out that she couldn't accept the idea that she could get better just by talking.

Bion: I suspect she is setting a kind of trap in order to find out what you think. I would be inclined to say something of this sort: "What you have just told me I could not possibly know unless you had told me. I am assuming that you are speaking the truth, otherwise we should have to consider why you tell me lies. As it is, you have drawn my attention to a mystery – you are feeling better when there is no known cause for it. We can now continue the discussion of this extraordinary problem." That doesn't commit you to saying that you or analysis cures people – I think that is nonsense. Certain people do seem to be able to make use of analytic sessions in such a way that they become more capable of working, more socially acceptable. But why that is so I don't know. The only *fact* I know is that when I have given an interpretation, I have either been wrong – which doesn't matter – or I have drawn attention to what, in my opinion, is already there. I wouldn't say that to the patient, but nor would I allow her to

manoeuvre me into a situation where I am agreeing that I have cured her or made her feel better. One could say, "Assuming that you are right about this, you ought to know how you feel, and therefore we assume that you feel much better. But so far we have heard nothing about why."

P: I tried to draw her attention to the fact that she always wants explanations and that she herself didn't know what happened to her between Friday and Monday. She said, "If I were to give explanations, I would suddenly get worse. My husband said, 'You were feeling so ill, and now you seem so much better. Dr X must be a very good analyst to have achieved that.' And I said, 'I don't even know how it happened, because he doesn't talk to me."

B: So if she is better it must have something to do with not talking.

P: She again said I was very tense. Then she complained that I was very hard with her. "If you don't give me any explanations I shall certainly get worse." I said I thought she was afraid that, since she was feeling so well, she had robbed me of something good.

B: How is it that you have become so 'tense'? It might still be the same answer: if she has taken a cure away from you, that would explain why you have no cure left. I think there is a suspicion that when two people come together they can't both benefit, either because it is 'only' analysis which is 'just talk', or because she will have to take something away from you, or you will have to take something away from her.

CONTRIBUTIONS TO PANEL DISCUSSIONS: BRASILIA, A NEW EXPERIENCE

1975

I find myself in a peculiar position because in some sense I must know less about this matter than any member of the audience. But in so far as I have concerned myself with an attempt to understand the way in which human character develops, I feel that it gives me a chance to contribute more to that particular way of looking at things. I am reminded of the fact that apparently the idea of Brasilia was formulated at least as long ago as 1820. The curious thing is that it then seemed to disappear, but we who are able to come to it one hundred and fifty years later can all look around us and see this extraordinary edifice which developed out of an idea. It is very puzzling to know why or how it developed at that particular date. One could say that perhaps the time was ripe for it; there were people who had studied architecture, the foundations essential for any particular building, and indeed of this city. This point may seem obvious, but when an idea is transformed into action it is as if the action commits the people who think like that to an irreversible course. If it were possible to look at this city and guess at a sort of reconstruction of the original idea, it could hardly be put more clearly than in the language used by one of the English poets. I refer to the *Areopagitica,* and in particular to one passage in which Milton says, "I see in my mind a noble and puissant nation." The remarkable thing is that that idea appears to be able to transform itself into actions. I have heard it said that another poet, Shakespeare, is the person who was really responsible for giving his people the idea of what they might become. How do these poets come to formulate ideas in a way which makes them fertile? If we could turn back the pages of time we might be able to see the primitive people who wanted to find some way of settling here. But it didn't have any marked effect because it seems that a very long time had

to elapse between the wish of those people, and the coming of others who were able to translate those ideas into action. Somebody must be able to sow a mental seed which is capable of germination. That is why the poets, philosophers and mathematicians are so important; they make it possible for an idea to become an action. Kant once said that intuition without a concept is blind, and a concept without intuition is empty. That phrase is particularly wide-ranging; it is one of these statements which, like a seed, germinates and turns into some kind of tree or forest.

To come now to something more immediate and practical: it doesn't matter very much what members of a panel think, but it *is* important if it starts sprouts of thought all over the place. This sounds simple, but in my experience it is not; in my experience these ideas can be stamped out before they have had a chance to develop. It would be nice to think that groups of people will form and devote themselves to the development of some idea which they have heard expressed during one of these meetings.

Milton, in the passage I quoted, talks about the eagle "kindling her undazzled eyes at the full midday beam". Can somebody living in this city, maybe in this very meeting, dare to kindle their undazzled eyes in the full midday beam? This idea is very old: in the *Mahabharata* (that part of it which is the *Bhagavad Gita*) Arjuna presses Krishna to reveal himself. Krishna agrees to do so with the result that Arjuna is blinded by the spectacle, but he survives. Is this significant, since it was written so many hundreds of years ago? By itself perhaps not, but it seems to be something which people in all ages have experienced. The religious mystics like Meister Eckhart, poets like Dante, and many others, had the same experience although they were separated by hundreds of years, by nationality, by race, and by language. So I think that you, the inhabitants of Brasilia, need to realize that this may kindle a candle which will shine through the world's prevalent darkness. I am not suggesting that this can be done only by psychoanalysts or poets or philosophers, but between them all they may be able to light a flame which illuminates the darkness of man's mind. I think we are more aware nowadays of the darkness; we do not quite so easily see everything in a rosy glow of optimism. But we must not allow the shadows and the shades to crowd in and destroy that small flicker of civilization which springs up here and there into a

supernova illuminating the darkness of the universes of galaxies. The situation is clearly serious and urgent. In fact the progress of science may have developed greatly out of proportion to the development of the humanities. This does not mean that it can be dealt with by putting an end to science. But nor can it be dealt with by putting an end to any of the other activities of the human mind. This is why the governors of states, of communities, are such important people; they can give the arts, sciences, and what one sometimes rather vaguely calls 'religion', a chance to develop – not simply to become a dead, undeveloping aspect of the mind which then decays, leaving a gap where some important aspect of the human mind ought to be.

* * *

The idea of Brasilia has been successfully turned into marble and stone so that there is a habitation for the people of the city. What is not so clear is how this city is to be adequately and appropriately inhabited, not only now, not only in the past, but also in the future. The fate of Brasilia, and probably the fate of Brazil, is being settled *now*, not by the housing of the population – all that the architects can do is to make it available – but by every single one of the inhabitants. There is no difficulty at all in individuals having a family, but those individuals have to make preparations long before that, long before birth – and long after it. It is not enough for *this* generation to be occupying Brasilia now; it also has to occupy it in such a way that something is left which will make it an even better place for future generations to inhabit. The spirit of a nation is very difficult to comprehend: we talk about these things and then tend to think that, because we have given them names, they therefore exist, that there is no need to do anything else. But nobody can opt out of 'naming' the present Brasilia and the future one – everybody is drawn into it, thereby starting a chain reaction.

Psychoanalysts have to do a great deal of work in order to be able to express an opinion of what constitutes the mental food that will propagate or make possible mental growth. This is the kind of thing which libraries have done from the beginning of time. But libraries from the beginning of time have also been burned down because they are such a terrible irritant; people hate having their thoughts stirred up. So a nation has to rely on individuals who dare to have ideas *and*

who dare to propagate them. And governments have to dare to make it possible for universities, libraries, the arts, to flourish. None of us here would have much difficulty in recalling situations in which the development of independent thought, whether scientific or artistic, has aroused powerful, destructive forces. Whether that happens here is being settled now; it is being settled by the fact that the government is apparently prepared to give assistance to the thinkers amongst this population. That is the most hopeful sign in a world in which there isn't a great deal of ground for hope.

* * *

Anything can be done with psychoanalytic terms – as I have good reason to know. I haven't noticed any particular lack of bigotry, intolerance and ignorance amongst my colleagues or myself. All one can do is to be vigilant and aware of the danger of assuming that a self-imposed characteristic may not have much to do with the truth. All sorts of people call themselves enlightened, or make excursions and experiments into the sphere of human activity, without apparently being touched by these same discoveries themselves. There is a sad passage in the biography of Max Planck: he said, of his difficulties when trying to elaborate quantum mechanics, "This experience gave me an opportunity to learn a fact – a remarkable fact in my opinion – that a new scientific truth does not triumph by convincing its opponents and making them see the light, but rather because its opponents eventually die and a new generation grows up that is familiar with it." So the last thing I would want to suggest here is that psychoanalysts are in any way exempted from the characteristics of the rest of the human race. We ought to know something about ourselves, and indeed we attempt to do so; it is one of our rules of training that students should themselves get analysed. I am sorry to say that, even so, it in no way precludes the possibility of the analyst being narrow-minded and intolerant. So I don't think that the spread of psychoanalytic theories is going to solve this problem. Why is it that one person is capable of tolerance, compassion, concern or respect for his fellows, and another isn't? I don't know. No amount of labels that he can collect and wear really affects this point. It is very sad.

A mathematician *is* able to prove a lot of things. Newton, for example, told Halley that it was obvious how the movement of the planets was governed. When Halley asked, "Can you prove it?",

Newton replied, "Give me two or three days and I certainly will." The 'poet' Newton made the discovery; the 'mathematician' Newton proved it.

We don't seem to be able to grow or develop to order, but we can find plenty of ways by which we prove that what we do is right – it is a curious aspect of the creative human being. One would like to achieve the kind of thought which might make it possible not to be deceived in that way. So even those few people who are disposed to explore the possibilities of psychoanalysis have a great deal to do; it cannot be assumed that it is a subject which has been settled, that it stopped at Freud in the way that the waves of the ocean might stop at the feet of Canute. The world of reality does not conform to the capacities of human beings; that is why it is so important that scientists and others – all of us – should have some respect for reality, and should not allow ourselves to distort our view of it.

* * *

There are limits to what can be done in the way of building a city which will reflect Brasilia. Is it a distorting mirror that clutters the inhabitants? Or is it a mirror that shows the inhabitants the faults and dangers which beset them? I am aware that if you are going to build a city, then you have to stick to certain disciplines and rules of building. But I don't know what rules of building you would stick to if you were going to create a city which reflected the personality or spirit of a people. Saint Augustine tried to do it with *The City of God*, which had a profound effect. In some ways it ushered in a dynamic philosophy and a dynamic psychology, not one which was so rigid or so clear-cut as the Platonic philosophy.

* * *

I am often reminded of the quotation, *si monumentum requiris, circumspice.*[1] Does anyone here want a monument? Certainly we can see one if we look around, but that is not what Brasilia is: it is a great city and it is waiting for somebody to come and live in it. People who complain that Brasilia is empty are really talking nonsense. It is supposed to be available for the people who are sufficiently great to live

[1]Inscription over the interior of the North Door in St Paul's Cathedral, London; attributed to the son of Sir Christopher Wren.

in such an edifice. It is not a monument to the past: it is an aspiration to the future – or so it seems to me.

We are not concerned with the *building* of this city; we are concerned with *living* in it. How are the inhabitants to grow up and go through the tribulations which appear to be inescapable? Milton, in *Paradise Lost,* describes his long sojourn in the Stygian pool, this frightening, dark descent, and "up to re-ascend though hard and rare". I don't think anyone can escape this. The only thing wrong with the magnificence of this city is that it might mislead people into thinking that they have nothing to do except just live in it, but they have to go through these painful spiritual, mental experiences of loneliness, anxiety, fear about the outcome. I don't see how there will ever be a population of this capital city fit for the problems which the future holds for the human race. They seem to me to be dark and threatening, and I don't think that any looking to the past is going to help except as a warning of what mistakes to avoid.

I cannot say how this is to be done – I don't think any of us can. Nothing short of hard work and thinking is going to solve that problem. Those in the university will have to work very hard indeed, much harder than getting through examinations and qualifying – that is a trifle. The real trouble starts after they are qualified, after they have grown up.

* * *

A psychoanalyst should not be particularly disturbed because patients cannot stand analysis, and leave. Some will think better of it later on, and come back knowing a bit more about it and trying to make some use of it. I don't think that the analyst should produce some form of simplified analysis for people who can't tolerate it; nor do I think that the authorities of Brasilia should try to adapt the shape of Brasilia to suit the people who can't put up with it as it is. By all means be open to criticism, but it would be a great mistake to allow the critics to dominate the situation and to degrade the standards of Brasilia because it is too magnificent, too much for them, beyond the capacity – as they see it – of the nation. It may be, like analysis, beyond the capacity of some people who discover that it is an unpleasant and harsh discipline. But it is not going to be improved by making the discipline less.

* * *

Certain people have undergone the severe discipline of engineering, or architectural, or mathematical training. I am not sure that if they had been asked why they were undergoing that discipline – say twenty years ago – they would have been able to give a particularly convincing answer. They could have answered in terms of their discipline – that they were going to be architects, engineers or mathematicians – but *now* we can have a strong suspicion that what they were all 'up to' was building a city. The kind of training that I have had leads me to consider a particular aspect of the facts with which I am confronted at any given time. But what I am stimulated to express, to formulate, may have very little to do with the ostensible reason for the stimulation. So when I see this extraordinary manifestation, the effect it creates on me is to make me feel that behind it there is an invitation and something which is responsible for that invitation – a reality which I would call 'the spirit of the Brazilian people'. It is an inadequate phrase, but I don't feel quite so dissatisfied with the idea that it is an 'invitation' as I do with any other formulation that I can think of, such as that it is a 'challenge'.

I suspect any invitation of having a fleeting nature. It may be difficult to see it, or hear it, or interpret it, and every individual will hear a different interpretation and a different invitation. It doesn't surprise me in the least that a great number of people dislike the invitation very much because of the suspicion that if it is accepted they will all be participants in having to fulfil a promise. That is a fate of which most people are frightened; it is subscribing to saying either 'yes' or 'no' to the invitation to participate or cooperate in a creative activity. What creative activity? Nobody tells us that; nobody knows what the response will be to that invitation. I would say that it looks like an invitation to greatness. What a nasty prospect that is! One feels like saying, "What, me? What, us? *We* have to be great?" It is so much simpler to say that we have a previous engagement and choose not to accept the invitation. But in this curious mental world that so fascinates me, there is no such thing as doing nothing – doing nothing is a response; it is a sort of acceptance of the invitation. There are no negatives in this world; every formulation is in fact a positive acceptance whether we like it or not.

* * *

One of the great difficulties in trying to assess what has happened in Brasilia is that we have to consider it *while it is still going on.* I suspect

that the city itself, in the way that it has come into being, is the visible part of an upheaval, an outburst of mental turbulence – rather like the kind of thing Leonardo often formulated in his Notebooks with his drawings of hair and water. He was aware of a state of mind which is by no means rare and which repeats itself over and over again; he could attempt to 'put a line round it'. There can be a conjunction of a whole number of people – a family, a professional family, a nation – and as an outcome of that coming together there is an emotional explosion. In some respects the same people who are responsible for participating in that turmoil are the victims of the same turmoil. It is like trying to make up your mind what it is that has hit you while you are being hit; it is still more difficult to do while you are not being hit, for then you don't know much about what you are supposed to be investigating or feel impelled to investigate. While the turmoil is in progress, however, there is plenty of evidence that it is difficult to assess that evidence. I am reminded of the statement that it is not difficult to be a *successful* general, but a *good* general has to be able to think while he is being fired at and bombed and shelled; he doesn't have to be very intelligent, but he has to be durable. The same is true of a nation which suddenly finds that its own collection of people has produced a city. In Milton's words, "Methinks I see in my mind a mighty and puissant nation rousing herself like a strong man after sleep, and shaking her invincible locks." I don't think any of us much like being a part of this mind that sees that kind of upheaval taking place. We wish that the strong man rousing from sleep would be so good as to go to sleep again instead of bothering us by tossing about and giving *us* bad dreams.

I say 'bad dreams' because it is impossible to participate in this kind of upheaval without having bad dreams. From the little that I know about history and the way in which minds, personalities and characters develop, it seems to me most unlikely that the people who are affected by Brasilia are going to have a nice time. They will have to do some thinking in these superficially comfortable circumstances which are not emotionally comfortable at all. Outwardly it is seductively simple, but anybody who is sensitive to the emotional experience is in for a very uncomfortable and unpleasant time – although as with some nightmares and dreams, they can apparently be turned to good account.

SÃO PAULO

1978

1

Presenter: The patient, an economist, is thirty-eight years old and has been in analysis with me for almost a year. He and his sister were sent, as children, to live with the grandparents because the parents decided to devote all their attention to the brother who is mentally deficient. The patient refers to himself as "an orphan with living parents". His physical appearance is good; he is well-mannered and is punctual. I have the impression that his contact with me has some ritualistic aspects.

Bion: What part of his behaviour seems to be symptomatic of a ritual?

P: His walk is rather mechanical; the way he walks to the couch and lies down seems like a well-finished product of something. I notice it also in the way his first phrases are constructed at the beginning of the session. For example, he breathes in deeply and then always says, "Very well, Doctor", and he uses certain expressions such as, "I have brought you some dreams today", or "I want to believe that we are going to work well today."

B: Why does he say they are dreams?

P: He simply tells me so.

B: It is one of these words which are so commonly used that people think they know what dreams are and speak about them without question. On what grounds do we say that the patient had a dream? And what strikes you about the patient's statement that he had a dream?

Member: I would first ask myself why he starts telling me that he had a dream.

B: Yes, it is an important question. We do not ordinarily say to a stranger, "I had a dream." So why does the patient come to see a

psychoanalyst and say he had a dream? I can imagine myself saying to a patient, "Where were you last night? What did you see?" If the patient told me he didn't see anything – he just went to bed – I would say, "Well, I still want to know where you went and what you saw." If the patient said, "Ah, well, I had a dream", then I would want to know why he says it was a dream.

P: I get the impression that when he says he had a dream, he wants to let me know that he has something very important to say and that I am going to be interested in it.

B: That I can understand, but when he says that, he is awake and 'conscious', as we call it. So – both the patient and you are in the same state of mind, and that is not the same state of mind as you or he are in when asleep. He is inviting you and himself to be prejudiced in favour of a state of mind in which we are when awake.

P: He has been taking his holidays either before or after mine. In the first session after his last holiday he apologized for forgetting to send me a cheque for his fees. Then he said he had forgotten to apologize because he was so busy during his vacation.

B: These are the problems this raises in my mind. I have already asked one question: why does he say he had a dream? I'll ask another: why does he say he is an economist? If he is an economist, why does he say he has forgotten to pay his account? Aren't economists supposed to know about accounts? This is a peculiar story: it doesn't fit together; these bits of news don't harmonize. Perhaps he thinks that psychoanalysis is a kind of religion and that analysts follow a ritual of three-times-a-week, four-times-a-week, five-times-a-week at such-and-such hours; and that if the ritual of the psychoanalytic religion is properly carried out, then the patient will end up cured. I would like to hear some more about this peculiar state of affairs.

P: I suggested that he was too preoccupied with himself to remember the account. Then he said that he was not worried or concerned about himself; the most important people for him were his wife and children.

B: This is again very peculiar. He says he isn't worried about himself; the only things that worry him are what I call 'facts'. As I understand that, 'facts' are things you can't do anything about. If there is something wrong with the patient, then I can understand that he might try to discuss it. But if there is nothing troubling him – and we know there isn't because he has said so – then these 'facts' are

nothing to do with us; we can't do anything about his wife and children, and we can do nothing about him because he's all right. So why does he come to you?

If you agree with me that we can't do anything about these 'facts', then what do we think we are doing? We could say that we might try analysing him, but if he has no worries about himself what are we supposed to do? Who or what does he think the analyst is? Does he think you are a surgeon? A physician? A priest? An economist? An industrialist? Does he think your business is collecting money from him? And if so, why has he forgotten to bring the money? I think I might say, "If what you say is right, I wonder why you have come to me. There must be some reason why you are spending time and money to come and see me. Can you tell me what you think I am, or what I do?"

P: It occurs to me that he thinks of himself as the analyst. The times which are productive and in which both of us can work are those when he becomes very upset, says I have confused him and he cannot put what I have told him into any category.

B: Why go to somebody who treats you like that? Why spend time and money on someone who 'confuses' you?

P: He frequently says that he comes to me because he thinks that I have something good to give him. But he feels he has to take possession of the ingredients of my life; he wants to know how I reach an idea.

B: I would be inclined to say, "I thought you said you are an economist. You seem to be behaving as if you are a psychiatrist or a psychoanalyst." What makes him think that you have anything valuable that you would want to part with, or that he would want to get?

P: He came to me after a former 'psychoanalysis'. In that so-called psychoanalytic treatment he conducted every session, and his 'analyst' was supposed to agree or disagree with what he said. He was therefore very shocked to find that I did not conduct the analysis in that way. He said that with the previous analyst he had known everything about himself but nevertheless still felt very distressed. With me he didn't know anything about himself or about me, but in spite of this he felt better – he thought I must be some kind of witch. When he first came to me he brought his 'psychodiagnosis' – his 'oedipal situation' and his 'mechanisms of defence' – and wanted to discuss it with me.

B: What an extraordinary story! Can he say what an 'oedipal situation' is? And what have 'oedipal situations' to do with psychoanalysis? It is an important question because it is the kind of thing we are liable to have said to us. People learn, if they are clever enough, to read books about 'oedipal situations', 'dreams', 'interpretations', and so on and so forth. And indeed they sound *just like* psychoanalysts or psychiatrists. But when these people who sound so knowledgeable and who use all the 'correct' terms – 'father figure', 'mother figure', 'oedipal situation', the whole psychoanalytic rubbish bin – are actually confronted by a psychoanalytic experience, they show great fear; the person who is so knowledgeable, knows all about it, becomes 'confused'; the mind which is so wonderful, cured, simply disintegrates.

One could say to this patient, "Why, when we are using – as far as I know – ordinary articulate speech, should you become confused? Suppose I am the patient that you, with all your psychoanalytic knowledge, are going to cure: why do you get confused? Either you have made a mistake in thinking that you know all about it, or you shouldn't be a psychoanalyst. You ought to take up something like economics; you shouldn't be coming to analyse me."

In the practice of analysis such a patient, who is apparently wide awake, sensible, rational, well-qualified, cannot stand the strain of being an analyst. Nowadays there is a chance that all of us will get more patients like this – patients who know *all* about psychoanalysis and are much superior to us poor analysts.

2

Presenter: The patient I am going to talk about is one with whom I have great difficulties. He suffers terribly during the sessions and shows his suffering physically – he sneezes, moans, sighs. He gets very desperate. And I always feel that I fail to understand what is happening.

Bion: What does he talk about when he behaves like that?

P: Very often he doesn't talk; he puts his head in his hands and says, "Oh, my God!" In yesterday's session he looked at me when he came in and smiled with a happy expression – this often happens – and then lay down. There was a long silence of ten minutes and during that time I tried to watch him.

B: When do you think the session starts? Are you waiting for him in the consulting room?

P: No, I fetch him from the waiting room.

B: How does the session end?

P: I say the time is up. I get up and he goes out. Often, after a very bad session, he looks at me, smiling, and goes out happily.

B: And you go out with him?

P: No, except once three days ago when the lights went out and I had to go with him with a candle.

B: Some patients want to prolong the session; when they stand up to leave they go on talking. I don't like giving interpretations then because that lengthens the sessions more and more – like a prolonged good-bye. So when I have said the session is over, I stop.

P: He once complained that he is the one who has to start talking in the session.

B: That is his misfortune. He might complain that the session

ends when he has a lot more to say and hasn't had a chance of saying it. Whatever you do, there are disadvantages.

P: After ten minutes' silence he started talking. He said that when he was coming up the stairs to my consulting room, and in his house earlier, he felt sure that he was going to fight with me. But when he arrived he felt relieved. "But now", he said, "I want to send you to hell – I don't know why."

B: What is your impression of this? I would like you to imagine that you are seeing the patient for the first time. Do you want to take him on or not?

P: I am doubtful that I would continue with him; I might suggest another analyst.

B: In a way every session is the first because people change: the two-hundredth session is still the first, but you are now prejudiced by what you have seen in the previous one hundred and ninety-nine. By then *you* may be sighing but he may not. This "Oh, my God!" is a state of mind. Whose state of mind is it? Who is feeling like that? Is it the patient? Or the analyst at seeing him again? Or is it his mother or father? Or is it what you are *going* to feel like? In other words, what are you looking at – a historian or a prophet? Is this a person who is writing with his body about past events? Or times to come?

P: He once said, "I feel you can't stand me."

B: You could say, "I think you are feeling that you are not taken in by the fact that I behave in a polite and civilized manner; that if I were sincere and honest, I would be feeling and acting in the way you suggest."

P: He continued, "I think you want to say, 'It's no good; go and look for another kind of therapy; analysis is not for you.'" I felt he wanted me to send him away.

B: This may be a reminiscence, something his mother felt – too tired to deal with such a troublesome boy always requiring attention, always expecting to be loved and wanted. Perhaps he had a brother or sister who also got tired of playing with him; or a girl-friend who didn't want to marry him. Similarly it may be that his analyst does not want to go on with the analysis when he wants to have more; or he doesn't want an analysis with this analyst but with a 'better' one. Or he may feel, "No, this can't come to anything because I don't want to marry this analyst – I have somebody else in mind." In any case the

analysis cannot end happily; patients don't 'live happily ever after' with their analysts.

These are just a few possible stories: which one shall we tell him? There are two people in the room – who is going to get tired of the other one first? And what is the game that is being played? When the number of choices is considerable, you can see that the chances of choosing the right one are loaded against you. You don't know whether to choose in terms of past history, or present, or future.

P: He was engaged to be married some years ago but broke it off. He does the same with his professional life. He is always changing jobs, always changing his choice of career. He was a surgeon; he left surgery to get scholarships in Europe where he spent three years. When he came back he worked in laboratory research. During the six months before starting analysis he changed jobs three times, dismissed from at least one of them for inefficiency. I don't know what he is doing now – the information I get is very vague and confused – except that he is taking a course in philosophy.

B: Now the situation gets a bit clearer. It is not simply a question of choosing his doctor, analyst, wife, father or mother; it is also a question of choosing his profession. But things are just the same; he has always been unfaithful to his chosen profession and has tried another. But the new one is no better than the old. Sooner or later he is saying, "My God, this laboratory!" Or, "My God, this medicine!" Or, "My God, this philosophy!" Or, "My God, this analysis!" At present he is doing all those things – he is confused and is saying, "Take all this rubbish and choose the best one from it." When he sighs, he is evacuating flatus; and when he talks, he is evacuating ideas.

P: Yesterday I asked him if he had ever considered that he has a head to use for thinking, not as a bowel or intestine full of shit. He said, "I'm full of shit."

B: He doesn't want to be to blame. So you can choose: a man who is full of care, trouble and worry (which is your fault, and the fault of father, mother, brother, sister, wife and children because they chose him), or a man who smiles and is pleasant, polite and civil (which is again your fault for making him carry this heavy burden of being agreeable and nice whatever he is feeling like). He doesn't want to work or to be cooperative and friendly whether he has a headache or is ill or tired. He could say that if you want to analyse him or marry

him, then you can't complain if you have someone who is tiresome and bad-tempered because he warned you that that is what he is like. His problem is how to avoid being responsible for his own behaviour, and how to find somebody who will take that responsibility.

Consider the ramifications of that: it is even the business of the job itself to be interesting. That is not unreasonable; one would like to choose work that is interesting. So – he tries being a patient; he tries being a baby; he tries being a child; he tries being grown up; he tries being a doctor; he tries – and so forth. But what he is looking for is a job that will be 'interesting'. Contrast that with this point: is it the *job* that has to be interesting? Or does *he* have to be interested in the job? There is a big difference.

P: At the beginning of the analysis he was absolutely convinced that I was in love with him and that I came to the consulting room because I wanted to be with him.

B: But it has to be a particular sort of love. You are exactly the person who would be interested in *him,* who would love *him* – not the person he wants to love. He doesn't want a wife and children he would have to look after; he wants to choose a wife and children who will look after *him.* He wants to choose a job that will look after him and provide him with a living.

When he says that he loves someone, what does he mean? Which *direction* is he talking about? When he loves his food, must the food love his digestive system, do him good? Or does he want to love the food in a way that would make it love his insides, would eat him back again from inside? In other words, he wouldn't mind a meal, but it mustn't give him indigestion or ulcers, or eat *him* up.

P: He often complains that his stomach burns.

B: I expect you have a similar expression in Portuguese as the English one: to be inflamed with love for someone. This love for the partner is like a flame of everlasting fidelity. But it is not the sort of flame that burns up this patient, gives him 'indigestion', or turns into a sort of cancer and starts eating up his insides.

3

Presenter: The patient is a thirty-eight-year-old man who has been in analysis with me for eight years. At the beginning of the session I am describing, he came in smiling as if he felt superior, condescending. Still smiling, he said, "I saw your name in the telephone directory and you are under the heading of General Practitioner." My impression was that this was something which made me inferior, although I didn't understand why this should be so.

Bion: It doesn't matter if you don't understand because the patient has only just started talking. And the previous eight years don't matter because this is a new session and a new patient talking to you. Unfortunately it is also true that he is an old patient; he was the same old patient when he was born – and maybe before then.

When you are observing the patient, you are really observing a live archaeological specimen; buried in the patient is an ancient civilization. The patient says it is quite modern – it is in the telephone directory. But it isn't only in the telephone directory; it is in the 'telephone' which goes back much further. It goes back further than his nervous system – *that* telephonic system which travels from the cerebellum down to the toes.

As with the archaeologist who uses a spade, at a certain point the spade must be put aside and a brush used to remove the mud. This patient is also carrying out an archaeological investigation of you. He doesn't use a spade; he uses his mind and he uses a very blunt instrument – a sense of social superiority. So he can discover that you are one of these inferior people like GPs – very poor class. That keeps him on top – that's fine. But what have *you* uncovered? With his blunt instrument he can make it very difficult for you to think. Nevertheless you don't have to be superior to him; you can go on looking at him,

listening to him, excavating his mind to see what sort of personality he is. He is afraid of what you might bring to light and make clear so that he could see it; he doesn't want this superiority disturbed; he doesn't want you to understand – but he is afraid you are going to.

We all have to be aware that patients are frightened of us. They are afraid because they think we are ignorant, and they are possibly even more afraid that we are not ignorant. This patient is afraid of you for both reasons: you don't know enough to help him, and you know too much to want to help him. And the previous eight years make matters worse; now that you know him better you may not want to go on seeing him; you may not want to help a person like him. The analytic experience is potentially a nasty one both for the analyst and the analysand, although the analyst is more used to it. It is like being at sea: it is just as stormy for both people, but one of them may not be able to stand the storm. Here it is an invisible storm; these are storms of emotion. Psychoanalysing a patient causes an emotional disturbance; sometimes it creates so much emotional disturbance that it is not even confined to the consulting room – the waves spread out to the patient's husband, wife, children or other relatives. So it is not surprising if they also spread to the analyst. It is not possible to be an analyst, any more than a sailor or a soldier, without knowing this turmoil, this storm which is raging. In spite of the apparent calm of this superior person who looks down on the analyst, we know that he is frightened.

When you get far enough to uncover the patient's psychotic capacity he may mobilize his relatives who will want to come to see you. Being afraid that you may uncover what he would call his 'madness', he may want to upset you so that you will stop analysing him.

As you come nearer to what he doesn't want you or anybody to know, he is bound to be upset, and he is bound to want to look calm. In a surgical operation we can anaesthetize the patient: in an analytic operation we cannot. On the contrary, we make him aware of his pain and try to tell him where it comes from. He tries to deal with it by saying, "I haven't got a pain; you have the pain." Or to put it in other terms, how awful to be a doctor whom society needs; how much nicer to be society which is superior to doctors.

P: I told him that I noticed he seemed very happy in feeling superior to me and in thinking that I was at his disposal – waiting

and expectant. He usually arrives early and has to wait for me, but this time I was waiting for him.

B: I am sure that he wants to make it clear how lucky you are to have such a cooperative, pleasant patient. The difficulty is, how are you to make this clear to him without appearing to be sarcastic? In the middle of this emotional storm you still have to be able to speak in a way that is not hurtful; you have hurtful things to say but you don't want to hurt. To fall back on a pictorial image borrowed from surgery: you have to use a scalpel to cut into the flesh, but you don't need to dip your scalpel into poison before you make the incision. So you have to denude your statement of any hostility or sarcasm – if possible – because it is bad enough for the patient to know the truth about himself without it being made worse by the way in which it is made clear to him. It is difficult because the patient is doing his best, without necessarily realizing it, to upset you and make you want to be sarcastic.

P: Do you have the impression that I spoke sarcastically?

B: No, I don't. I think he would have reacted differently if you had. You can always see from the patient's reaction if your interpretation has something of that kind wrong with it; unconsciously the patient can give you a clue as to whether you are on the right track or not.

P: I think he agreed with what I said. He gave a slight smile. But immediately afterwards I had the impression that he was troubled.

B: You have the chance of observing these things you mention. It is like being able to listen not only to the words but also to the music; it is not simply what his words tell you, but also what the little facial muscles tell you – something that is very difficult to describe to another person. It certainly sounds as if you were getting through to him to a point where he was not comfortable. We hope, of course, that the patient will feel better, just as we hope that a patient will feel better after a surgical operation.

P: He then seemed to change the subject and asked, "What time is it by your watch?" I had noticed that his watch was slow, but I didn't consider it at the time although I remember it now.

B: I could ask: what time is it? And whose watch are you going to use? Shall I look at mine? Or the calendar? Is it April 5th? 1978? 1948? 300 BC? What *is* the time? Where have you got to with this

patient? What age is he? We know he could say that he is thirty-eight, but what is the date of this material you are discussing? Apparently it is *now* – but one wonders. Is it geological time? Or cosmic time? Is it historical time? We have not yet found out what analytical time is. Perhaps someday there will be a psychoanalytic calendar by which we could date the material. Was this patient born late? Was he post-mature or pre-mature? It is difficult to find out; even a mother is liable to forget that it was a painful labour because the baby was, say, a big one. If the baby is premature it might be an easy birth but a very difficult survival.

As I say, I don't know what calendar or watch we use for psychoanalysis. In historical time we talk about BC and AD; are we going to talk about 'Before Freud' and 'After Freud'? It is quite artificial, but might be useful.

4

Presenter: The patient is thirty years old, a university departmental director. He came for analysis because he had a problem with premature ejaculation. He has a phantasy of soon becoming President of the Republic.

I am reporting a mid-week session. He arrived punctually as usual, wearing a stern expression – also as usual – and was silent for a while. Then he said that he had been choosing what to say about something that was causing him great anxiety: a friend had told him that a former girl-friend of his had returned from abroad.

Bion: Supposing you were God and said to the patient, "Right – go on 'President of Brazil'." Would that be a premature ejaculation for him?

P: It could be – he is always ahead of himself, always puts the cart before the horse.

M: Do you think that the patient's silence was related to his fear of premature ejaculation?

B: Yes, and I think his attention could be drawn to the fact that his fear is of such a kind that he has to go to the opposite extreme.

P: When he got home that evening his wife was waiting for him in bed, but he was so disturbed by the news of the arrival of his girl-friend that he didn't go to bed and decided to watch television until three o'clock in the morning, although he knew that his wife was waiting for him. He said the programme he was enjoying so much was the presentation of the Oscar awards; he could see all the stars he admired so much.

B: We all think we know what 'television' means, but we forget that it actually means 'vision at a distance'. It is all right to want to be President if it is far enough away, but not if someone says, "All

right – you go and be the President." It is all right to *see* someone having intercourse, but not close to. If he has a wife, he can see the couple having intercourse but he is one of them. He may not be much better at having a loving relationship with a wife than he would be at having a loving relationship with the Republic. He is always ahead of himself, as you have described it; he is not simply having a conversation with his analyst; he is also watching and listening to that conversation.

P: I told him I thought he was approaching me with great caution so that he would know what he was going to tell me and what I was going to answer. I said he enjoyed watching himself and his analyst in the same way as he enjoyed watching television and discussing ideas; and perhaps that could be a masturbatory or voyeuristic attitude.

B: Yes, but that means that he can be afraid of what he would say if *he* were the analyst. That is why he is afraid of what you will say. It is not a question of being President of the Republic, or the husband of his wife; it is a question of being the analyst of his analyst. If he knows so much, you might say, "All right – you be my analyst – I'll be your patient." This would also make him afraid of what he might say if he didn't think very carefully. It is much easier to be the analyst at a distance – in time or space – but not when the two people are in the same room at the same time. The same thing applies to being in the same room at the same time with the girl-friend. It is worse still if the girl-friend has become a wife and he might have to become a husband.

P: After my interpretation about the possibility of a masturbatory or voyeuristic attitude, he choked and coughed and said, "Mm . . . mm . . .", babbled, and then said, "Why did you say that to me?"

B: Now – which intercourse are you witnessing? The 'babbling' may be a premature verbal intercourse; it can sound just like talking. A good actor can act *just like* a king, a queen, a president – anybody. But not *the* President. Or you could say, "Yes, you can be just like an analyst, but not *the* analyst." I think this patient is talking like the analyst, but that is not the same as giving interpretations. Your difficulty is how to make this clear to him without making him feel foolish. He can be afraid that you may make him look silly or stupid; he can be afraid that his wife may make him impotent – she can be a better mother than he can be a father. But that depends on whether

he feels that the relationship is one which is intended to show who is top, who is first, who has won, rather than a loving one. It takes time to learn about passionate love, and one of the pair may reach this state before the other.

This patient prefers to watch television rather than to get into bed with his wife; he may prefer to have an analysis as a way of putting it off, as a protection against the marriage bed. Yeats wrote, in his poem 'Solomon and the Witch', ". . . Maybe the bride-bed brings despair, For each an imagined image brings, And finds a real image there". We haven't words for the real thing, the thing itself. There is always the danger of falling back on 'psychobabble' in order to sound like a real analyst.

5

Presenter: I have not prepared a case for presentation –

Bion: It is just as well to get used to the fact that you are unprepared. There is nothing more to be said about what you are prepared for; what you know, you know – we needn't bother with that. We have to deal with all that we don't know.

P: I would like to talk about a patient, a young woman of twenty-five, who has been in analysis with me for a few months. She insisted that she wanted to be seen by me so I arranged an appointment. When she arrived I was impressed by her appearance: everything about her was like spring, but the story she told me about herself was not, and certainly did not accord with my feeling that she was charming and full of love. I thought I would like to accept her for analysis but she couldn't afford my usual fee and didn't want to ask her father for the money. So I lowered my fee so that she could have five sessions a week.

B: This is a very important point. We never know anything whatever about the patient's financial capacity – nothing. What we do know about is the bill we shall get tomorrow at the supermarket; it is no good saying, "Look, I can't pay you for this food, but I've got a very charming girl patient, so will you give me the food free?" You cannot really say that you will lower the fee – or at least you can say it, but whether you can afford it is a much more serious matter. Although it is difficult to know how much money we need, we can have an idea of what it costs us to remain in existence. A patient can say, "I may not be able to pay, but I want the very best doctor, the very best psychoanalyst. I don't want polluted food – I want the best." But who is going to pay for it? The apparently simple request made by this very attractive girl means that you are invited to feel she is

worth paying for – in other words, seeing her for less and thus paying the fees she can't pay. If you are very wealthy or have independent means, you might *appear* to be able to pay the fees. But a father or mother who says to the son or daughter, "I'm very rich – you can have whatever you want; do what you like", cannot have any feelings of love or affection for the child. Whether we like it or not, sometimes we have to say, "No".

P: The experience I have had with this patient is the opposite of my first impression.

B: Quite. As Shakespeare says (in *Macbeth*), "The primrose way to the everlasting bonfire." The road is lined with primroses; the road to the analyst is lined with beautiful girls and boys; it leads to hell in the end.

P: I think she is doing what she can to make my work impossible – not unconsciously, but deliberately. She never has anything to tell me apart from giving her opinion of herself.

B: Thanks to psychoanalytic theory, everybody knows all about psychoanalysis. I myself create just such difficulties: every lecture I give increases the supply of theories about psychoanalysis. One hopes that it is of some use to analysts, but in fact over and again it makes things more difficult. People are able to throw these technical terms around: they don't feel angry, they feel 'paranoid'; they don't feel depressed, they are in a 'depressive situation'. Did you ever hear such nonsense? It's a kind of hell of our own making, a sort of psychoanalytic hell.

Can you still find a patient buried somewhere amongst all this rubbish? This patient can put on a suitably spring-like costume, this cosmetic cure, but she can also put on this mental cure; she can wrap herself in psychoanalytic terms. So we need to get through these layers and layers of 'cure' to reveal the suffering patient. It is no good saying to her, "Give up all these cosmetic appliances – I want to know where it hurts." But if we listen long enough we may be able to 'see' where it hurts.

P: At the beginning of the analysis she was very disturbed, distressed, and complained of a lot of pain. She wanted me to prescribe medicine to stop her suffering, but in the sessions it was always very clear that she was not suffering physical pain. I felt that she wanted to involve me in what was happening outside the analysis.

B: My impression is that this girl is suffering from a very bad attack of cure. She can never get properly treated because she is so cured; she has learnt all the tricks of how to be exactly like a charming little girl whom everybody loves. But she knows who she really is, and she suffers this painful fear that the analyst also will think that she is this beautiful spring-like creature. A conflict is bound to arise because she doesn't know whether to be what everybody says is a 'good girl', or to say, "No, I feel horrid and I'm going to be horrid – I've never had a chance of being nasty." From what we have heard, I think that she is getting relief because she is able to be nasty, she is able to give her analyst hell. But so far you haven't broken up or broken down, or said good-bye – or, "You're cured", which is just as bad. So the very fact of feeling relieved is indistinguishable from feeling far worse.

To give a dramatic example of what I mean: the survivors of a shipwreck are drifting on an improvised piece of wreckage. They aren't frightened; they are just hopeless and they are starving. But when a ship is sighted, anxiety, fear and terror break out; the calm of despair disappears. Theoretically the position is better; they are within reach of rescue and safety. But instead of feeling better they feel worse.

It is similar with this girl. The possibility of being able to be horrid can bring a kind of relief which is also horrid; it is worse than being in a state of despair. The person who is in despair doesn't show any particularly marked feelings, and would sometimes like to be left in that state because it is less upsetting than the possibility of rescue.

This patient may feel, "Yes, this is what I want; I don't want to be treated as if I were a beautiful, loving creature. I would like somebody to know that I'm hateful and horrid." But at the same time there is the fear that if she believes that, she will suddenly find that you don't. You might say, "Oh well, if you are such a nasty creature, I won't see you any more."

P: Now I understand better something which surprised me at the time. Whenever I give an interpretation about something 'nasty', she laughs, secret laughter like a child who has been discovered doing something naughty and does not want to be seen laughing. It seems to give her pleasure.

B: If she values herself, she knows that while she wants to be

cured, she would also like to retain her 'self'. I use this term because it hasn't already been 'polluted' with meaning and associations. If I say 'her body', or 'her mind', we all know what that means but it doesn't give an idea of what it is that this patient values. Fundamentally, basically, tucked away somewhere, is the feeling that she has a self that she doesn't want interfered with – improved, cured, or anything else. On the way to finding her self, it would be useful to find a fulfilled self. A man or a woman cannot be fulfilled unless they have found a mate. Then potentially they can become fulfilled if these two personalities come together mentally in the way that their bodies come together. On the way to that it is possible that analysis might help. But the analytic relationship is different; it is not the fulfilled one. It could be called 'transferent', 'transient', not permanent It is like a lodging-house you find on the way to somewhere; it could be a stage on the journey towards a real communion between two people. It is useful to remember that 'transference' also means 'transient'; it is not *it*. I have to use a word like 'it' as the best way of talking about the real thing, the thing-in-itself. In this work one has to fall back on these 'transient' expressions.

There are all kinds of transient situations: a boy can love a boy-friend; a girl can love a girl-friend. But after a time it becomes rather unsatisfactory; they can't be married. Nevertheless it may be a stage on the way. Masses of laws, rules, conventions might help someone to find the real thing, but very often they can be a bit of a nuisance. That is why it is useful to allow a patient to say how much she loves her girl-friend; any suggestion of homosexual behaviour kills the growing shoot, for being able to love somebody who is just like yourself can be a step on the way to something else. We cannot say that we ever meet the 'perfect couple', but sometimes we can feel that a married couple get close enough to it to remind us of what that state might be.

P: There was a time when I had a feeling that she was having a homosexual relationship, but when I spoke of it she didn't mention it again.

B: That may have been because you had made it clear enough, and once something has become clear there is no need to talk about it any further. That is one possibility; another is that she dared not speak about it again. What language are we to use to explain to patients what they are talking about without giving the impression that we

either disapprove or approve? We are not expressing an opinion about whether something is good or bad – that is up to the patient.

A patient may make no reply at all to an interpretation, so you can get no idea whether it has had any helpful effect or not. But if you go on listening, you may find that the patient's whole mode of conversation alters. The tone of voice changes; the tension in the vocal cords disappears. You don't then need to be told that your interpretation was correct – you know it was, because the relationship between you and the patient has altered completely.

It may nevertheless be very difficult to put up with not giving all the many other possible interpretations. We are always dealing with an unknown situation, not what we or the patient know already. We may have seen the patient for ten years, but today's session is a new one.

M: Analysands who are training candidates, psychologists and other therapists, often think they know everything. One gives an interpretation – they know it already.

B: Some of the saddest words one hears are, "Yes, I know; yes, I know; yes, I know." It is terrible to have a patient who says that all the time.

6

Presenter: The patient, a fifty-year-old man, has been in analysis with me for a year. His background is a simple and modest one, but he is a very interesting and intelligent man. The session I have chosen shows the chief aspects I have noticed in my contact with this patient.

He came in, shook hands with me and said, "Good morning, how are you?" Then in a complaining voice, "I've been up since four o'clock. I've been thinking too much. My entire life has been like that – always thinking, thinking. I can't stand it any longer. I've also had problems with impotence – I'm worried about it." He continued, "When I arrived at the central bus station" (he comes from another town for his analysis) "I ate a meat roll, some pears and two tangerines. I didn't eat the cellular part of the tangerines because I don't think it is digestible. Nevertheless I now have indigestion – they are heavy in my stomach."

Bion: He is always thinking, thinking. Where? In his head? Or in his stomach? In the alimentary canal? Or with voluntary muscle?

P: That reminds me: in the next session he said, "I ate fried manioc and steak for lunch, and they are still inside my head."

B: Mental indigestion.

P: I have the feeling that he digests thoughts with the alimentary canal, and food with the head.

B: I would remind you of something else which may be similar. Somewhere inside the head is the 'rhinencephalon' – the nose–brain. Why is that? Do our noses think? Have our noses got brains? Why did the early anatomists call it the 'rhinencephalon'? Where did they get that idea from?

Fishes use the sense of smell as a long-distance receptor; sharks and mackerel, for instance, can smell decaying matter a long way

away. As embryos we go through a state when we are like fishes living in a watery fluid before we are born. After birth we carry this same watery medium inside our nostrils so that we are still able to smell when in a gaseous medium – air. If this happens when we change from being a foetus into a new-born baby, does something similar happen when we change from being an unthinking animal into a thinking one? Conversely, is there a time – as with this patient – when we give up trying to use our voluntary muscles and start thinking instead? Is it possible to be thinking too much? Is it possible that we lose the use of our limbs? Is it possible that we lose the capacity to use our digestive system as might, for example, a patient who is so anxious that he begins to have gastric and duodenal ulcers? Perhaps we shall be able to answer questions of this kind through an analytic investigation.

P: He continued, "I know life is a habit – I have learnt that already. God help me, I don't want to make analysis a habit. I have read so many books that people told me to read, and I've been forcing my personality, trying to keep all those things in my head."

B: Most people have become used to the idea that someone will 'cure' them – physically or mentally. And they have so often heard that 'there's a good time coming' that they don't want to hear it again. Nevertheless, something is making this patient think that perhaps he can hope that psychoanalysis will solve the problems which have never been solved, and which he has had to keep within himself. But he doesn't want to get married or devoted to psychoanalysis or psychoanalysts. At the same time he doesn't want to be disillusioned – he is too used to being dis-illusioned – and he doesn't even want to believe that psychoanalysis might help.

M: Do you think he has a religious attitude?

B: I think there is always a religious attitude, and the religion is always changing. At some time the god might be a footballer like Pele. Now the fashion is a psychoanalytic religion – the great god, Freud, and all the lesser saints. I don't think this patient wants to adopt the psychoanalytic religion or the psychoanalytic pantheon of gods and saints. I use the term 'pantheon', but don't forget that it always also means 'pandemonium'; every demon has its accompanying saint; every saint its demon. In the same way every cure has its accompanying disease.

M: Do you think that this patient's anxiety about his stomach

refers to a symbolic system that he has been unable to develop, or does he think of his digestive system as a god?

B: It is possible to speak of someone having 'his belly as his god'. Similarly we can say that people have as their god the intellectual life. For all this patient knows, psychoanalysts are just like that; they have made thinking into their god and ignore all the rest of life. Indeed, I think it is possible in dealing with anxieties, for us to appear to mean that there is nothing to be anxious about. But if a patient is frightened of being robbed or murdered, we think that it is better to be aware of that fact, and aware that there is something to be frightened of, than to pretend that it doesn't exist by not thinking of it, getting rid of it by pushing it into the unconscious where it will fester and grow.

What is cropping up here is not a real disagreement between the patient and the analyst (that is only part of it), but a disagreement between the patient's alimentary canal and the food, *and* between his mental alimentary canal and his mental nourishment – neither of these being endo-psychic conflicts. As well as that there is a disagreement between his alimentary system and his mental system. His mind feeds on nourishment provided by thinking too much, but his alimentary canal gets ulcers. In other words, he is so anxious that he doesn't digest his food properly.

In analysis we get nearer to a disagreement between the patient's ability to think and his ability to exercise his muscles – voluntary and involuntary. It is this conflict – now an endo-psychic one – about which we can do something; all the other conflicts are not affected by us; we can do nothing about them. For example, we cannot stop a patient from drinking so much alcohol that he poisons his system.

This patient may not be altogether wrong to be afraid of thinking. There can be such a thing as too much cerebration, the cerebral hemispheres used to the detriment of the sympathetic or autonomic system. And so the marriage between this patient and himself has never really been consummated. He is very glad to be hopeful of analysis, but if he has been starved of mental relief, what starts as hope rapidly becomes greed.

7

Presenter: The patient is a woman of forty who dresses as if she were much younger. She is French and speaks Portuguese with a strong accent. She has been in analysis with me for only two months, four times a week, but consulted me from time to time for about a year before that. When she first came for an interview she was very excited and happy because I had an hour to spare. Just before starting analysis she went to Europe on holiday. In London, amongst the crowds, she suddenly felt ill and frightened of being alone, frightened of something happening to her with no one to turn to.

Bion: This is a fundamental point. You can be 'all alone' with yourself; 'all alone' with your analyst; 'all alone' in a crowd of people in London. It is a curious combination: being all alone *and* dependent on people and things not you. We seem to be the kind of animal that has to have a society; we depend on it and are all alone at the same time. It is true at the age of forty, at the age of four, and at the age of nought.

P: The need always remains with us?

B: I think so. It is something to which the analyst tries to introduce the patient who has either forgotten it or has never been conscious of it. It is like having the experience but never being aware of it.

P: Her father died four years ago and her mother one year ago. She is an only child and had lived with her parents for some years prior to their deaths. She told me that since her mother's death she has kept her parents' bedroom intact; she has never moved any clothes, furniture, ornaments or photographs.

B: The advantage of 'the facts' is that they make it easier to talk about the furniture of the room than the furniture of her mind or character. But it is a step in that direction; it is a way of 'getting

to know' who she is. It is a sort of 'transient' relationship; a sort of 'transference'. It is felt to be more bearable to know your self than to be ignorant of your self. But on the way to knowing her self it is easier for this patient to know the furniture of her house. She might get to know the furniture of her mind in time.

P: She was married for one year when she was seventeen, and had a child. She said she couldn't stand that life, being tied to the child and the home; she wanted to travel and enjoy life. She left her husband, and his family kept the child. She went abroad where she lived alone for some years. She has never seen her child since, nor is she interested in doing so.

B: I think she is afraid that if she goes on with these conversations with you she will get to know herself as a child; then she may think that the clothes she wears are not appropriate to who she is now. That is easier for you to see than for her.

The feelings of a mother for a son or daughter can be very powerful. So what has happened to them? She is hoping to escape from them by moving about the surface of the earth, but whether she can really escape is a different matter. There must be some reason why she comes to see an analyst, but I don't suppose she knows what it is.

P: I have the impression that she spends her life escaping.

B: She is probably more expert at that than at anything else.

P: Last Monday she came to the session looking very miserable and said, "I feel so lonely. The week-end was like all the others. I am worried about the future. I feel more and more alone all the time. Yesterday some friends took me out, but I got no pleasure from it at all. They were very kind, but what help was it?" Then she wept.

B: I think this is again part of the fundamental story that she can't tolerate being all alone with her self even when she is with other people. This 'self' won't leave her – it goes with her. But we don't know what this 'self' is – it certainly isn't a self that she wants to be alone with, so she is always reaching out for somebody else. If she couldn't come to you she would certainly go to someone else; if she couldn't find anyone else, she would find a crowd of people in London, anywhere where there are masses of people so as to avoid being aware that she is with her self whether she likes it or not.

It is difficult to describe what she is talking about, but I feel it is a sort of 'urge to exist'. And this urge is completely indifferent to human beings; it doesn't care whether we die in childbirth or in any

other way. Her parents' urge to exist forced them to give birth to a child whether they wanted one or not. So she herself is a product of that same urge and is at its mercy. She is frightened of being all alone with that urge to exist which doesn't mind what happens to her – it is completely ruthless. And she is terrified of being a slave to the urge as her parents were. In a similar way bacilli and viruses are completely indifferent to human beings. If we are wiped out, another kind of 'thing' will exist instead.

P: Something like an 'incarnation' theory?

B: Yes. Or in*plant*ation – plants will do just as well. It is not only the bacilli, but also the cocchi; not only animal but botanical life. Recently it has been suggested that there is a form of animate object which is neither animal nor vegetable.

M: Where would you put what Freud called 'the instinct of self-preservation'?

B: One could place that in the human being because it is the *human being* who wants to go on existing. But this impulse to which I am drawing attention, and of which I think this patient is frightened, doesn't mind what happens to her provided life goes on. . . .

8

Presenter: This patient has been with me for thirteen years. At the beginning of the analysis I didn't know why he came because he didn't seem to have any complaints and apparently knew everything. He even asked me to read several books, and as I was interested I did so.

I have the impression that the analysis falls into three phases. The first was when symptoms and complaints started to appear and he wanted to understand exactly what I said. He brought a dictionary to the sessions and would look up various words I used. Then he brought an etymological dictionary also. I tried to show him that all his efforts were really an attempt to avoid understanding what I was saying.

Bion: What language is being used by the analyst and by the patient? The relationship seems to alter when the patient has 'symptoms'. Who thought they were symptoms? The patient? Or the analyst? Who *called* them symptoms?

P: I used the word as a characteristic of the patient at that stage.

B: Did the patient think they were symptoms?

P: At first he couldn't accept anything that might mean he was ill.

B: Yes, I understand that, but what has happened to make him think that there are any illnesses?

P: For a time, both before and during the analysis with me, he tried several different kinds of treatment such as group therapy.

B: The questions I am asking are very difficult to answer. What is going on with this patient? There is no physical illness; no mental illness. But there is a great outbreak, an eruption of treatments and

cures. Would you not begin to be suspicious that there must be some diseases somewhere? Why should there be a concentration of cures and methods of treatment in one place? It seems to me that we have to consider that there is something wrong. What you have been describing here is not an outbreak of patients, but an outbreak of analysts wanting to cure you. You are suffering from somebody who has nothing wrong with *him*, but who has a whole lot of books with which he can treat *you*.

Let's hear some more about this curious 'treatment', this outbreak of cures.

P: In the second phase I noticed that he was worried about time and space. For example, he wanted to take a lot of physical exercise. He spent more than thirty minutes of every session running up and down the consulting room, and spoke only after this seemingly fixed length of time.

In the third phase he continued to be worried about the meaning of words, but now expected an absolutely exact sense of the words I used. If I mentioned this to him he became violent and even broke two chairs.

Although he seems to be getting worse in the analysis, in his social and professional life he is getting more and more successful. He has married, bought apartments and cars, and has had written work published. Perhaps he leaves all his bad aspects with me while becoming successful outside the analysis.

B: Most patients don't believe that they have mental pain. This patient hasn't any troubles, but if he doesn't know that he is ill, it also means that he doesn't know when he is cured either. He has to know something about mental pain and mental health.

P: I suspect that he has provoked in me a response similar to the outbreak of treatments. There has been an outbreak of supervisions. I have even been abroad for supervisions on this case, and have had three years of supervisions here. I remember that one supervisor said I should read Piaget and other authors; I became even more confused – the illness was transmissible.

B: It is a puzzling situation: the patient has nothing the matter with him; he has become better and better, and more and more successful. But the analyst has become worse and worse.

P: Even financially the pattern has repeated itself: on the grounds

of hardship he paid reduced fees. And I have spent a great deal of money on travelling and supervisions.

B: The patient gets richer and richer; the analyst either stays as poor as usual or becomes poorer and poorer. The patient gets cleverer and cleverer and becomes successful; the analyst gets more and more ignorant and has to have more and more supervisions. It reminds me of that theory about the baby being able to evacuate its mental troubles into the breast or the mother, in the way that it can evacuate urine and faeces. The baby gets well, but the breast or mother gets ill and dies. That's all right if it is Melanie Klein's theory of projective identification. But this man isn't a baby, so although I am *reminded* of the theory, it isn't right; it doesn't fit this story in which everybody does so well except the analyst.

Why is it that the more experience psychoanalysts have, the more they realize how ignorant they are? What is the disease which causes us to realize how ignorant we are, and then to have to have more and more congresses, conferences, supervisions, analyses? I think the disease is a mind. Once the human quadruped started standing on its hind legs it had to become an acrobat. And the more civilized we become, the more difficult it is to behave in a civilized manner. The moment we become involved in thinking, we have to learn how to think properly; the moment we learn to stand on our hind legs, we have to learn how to stand on two legs, not four. When we have learnt that, we have to keep both those legs healthy and strong; the moment we find we are thinking, we have to think clearly. That is never-ending – the more we learn, the more we shall find how ignorant we are. You will never know what this patient's troubles are, but you will certainly know what *yours* are. To take an exaggerated example: in war you can know that you are terrified, but you don't know anything about the enemy. The enemy always seems to be well-off, brave and trouble-free. Psychoanalysts know where it hurts. It is easy to envy people who are wealthy, and have no troubles or difficulties, but we are supposed to know ourselves, our characteristics; we are not allowed this easy cure of looking and behaving as if we had no troubles. We are also supposed to be like leaders. Officers aren't supposed to run away in war, nor are they supposed to be so stupid that they don't know that it is dangerous. We know that these neuroses and psychoses are not just imagination – they are real. And we have to judge

how to tell the patient the truth about himself without frightening him.

I don't think this patient knows why the analytic discussion helps him to improve, to get better. But he does know that he is better for having discussed these matters with you. So he wouldn't like you to stop seeing him. That is why he has been coming for thirteen years; and that is why he would probably come for thirteen more if he could.

9

Presenter: The patient is an eighteen-year-old girl who has been in analysis with me for five months. Her parents, who came to see me first, said they were very worried because she was refusing to eat. She had been in treatment for a year previously with a man analyst, but had asked her father to find a woman analyst instead.

Her illness appeared to have begun when she was fifteen: she didn't want to be fat, although she was not in fact overweight. She had always had a beautiful body – as both she and her parents told me – but in order to be fashionable she wanted to be thinner.

She had had a boy-friend who lived a long way away from her home town, but she stopped seeing him and only kept in touch by letter. When she eats she prepares the food herself; she can only eat one egg or a little fish, and has the feeling that her stomach is unbearably full. She also takes strong laxatives – as many as fifteen tablets in a few days. She told me that she feels addicted to these pills which act as tranquillizers.

When I first saw her she aroused my sympathy. She shook my hand formally and said in a tense voice, "I want treatment because I am afraid I can't stop something that will kill me – but I don't know what it is." Later she said that she was full of aggression, that people feel she is very arrogant, and that the only impression she can give to other people is one of coldness.

Bion: She feels very beautiful, like a distant star; it glistens like a diamond, like steel; it is very far away – and useless. The same thing applies to the beautiful woman, the beautiful queen whom nobody would dare to approach. If you did approach her you would find she was sterile. And somehow she knows this. On the other hand, she fears that she could become pregnant, and then her beautiful body

would swell up, she would no longer be athletic, no longer able to compete in a sort of Olympic Games.

I think this story centres on the feeling that she is a person of no importance and that she is the slave of forces which don't care what happens to her.

P: She had a dream: her bitch was pregnant and she felt that the animal was experiencing the same feelings as she does when she evacuates.

B: It is entirely true.

P: She said, "When I went to pick her up, I saw she had been changed into sandwiches."

B: It is in line with the feeling that there is an urge to exist; it is felt to be something which doesn't care whether you are a dog, a bitch, or a beautiful woman – it is completely indifferent. The mother may die, the offspring may be eaten up, but all in the service of this force. If the human race blew itself out of existence with the neutron bomb, the force to exist wouldn't mind in the least – it would be just one more discarded experiment. So the patient can be afraid of being used simply as a means of perpetuating existence.

I don't think it would be the slightest good saying that to the patient, but it is something that would be useful to me if I were analysing this patient because I would expect everything to fit into that basic theory. I would expect it to crop up all the time – the patient waging war against this force, wanting to remain a person, a beautiful person, and not liking being a slave to that force, that power, that energy.

P: She always complains that she feels she has to be a beautiful daughter, a tender child, always smiling. She feels that her father invades her privacy and controls her, but at the same time she tells me that maybe it is not true, maybe it is only her feeling, maybe her father is suffering because of her illness. But when he is affectionate and tender towards her, or touches her, she rejects him.

B: I think she feels that her father also is an instrument in the progress of existence. I use the word 'existence', but I am trying to describe something which has no human characteristics. If the father is a slave to this same power, then these little rules about incest don't count, and if he submits to that force he will unhesitatingly seduce his daughter into producing more babies. There was a time when the pharaohs had incestuous relationships as a privilege. Nowadays it is

not fashionable but it still exists. The force behind it is very powerful, much more powerful than the sexual urge or sexual pleasure – those are simply things which we are aware of as human beings.

This patient would be afraid that you are just one more of these objects which are slaves to this power; or alternatively that you are also engaged in a hopeless war for individual existence against this massive force. It seems that she has found no way of mobilizing any resistance against that kind of omnipotent drive. I think all her problems are related to this one; all the individual problems are aspects of the same thing. It is like looking at one's hand: looked at through a microscope one sees individual cells, but they only add up to a totality we call a 'hand'. The individual piece of life – whether it is a dog, or a plant, or a human being – is simply one little particle in this total existence. The force doesn't mind what happens to it any more than we mind what happens to single cells of our skin which we shed and don't even know we have worn them out.

The patient knows nothing of this in any conceptual form. She probably thinks she is beautiful because she wants to be. But her beauty has very little to do with her – it is simply a way of leading her to be seductive so that somebody would want to have intercourse with her. She herself, unaware, is aiding the process; the more beautiful she is, the more likely she is to be used as a mate. Her problem is how to be beautiful but unapproachable, on the grounds that she is *so* beautiful, *so* majestic, that nobody will come near her.

P: Sometimes she tells me, "I shall only recover my health when I want to be well again", as if she can control her illness.

B: She may not be able to do that, but she can control you. She can get you to agree that she has that power; she would like to have the kind of analysis in which you would say, "Yes, you are quite right; you have all that power, you are potent, you are omnipotent."

P: When she has to go to see the physician, she is very anxious. She says that she doesn't believe he can do anything for her.

B: A patient like this feels she has no character, no opinions of her own, no feelings of her own. So she is frightened by examination, whether it is a temporary one by a doctor, or a longer one by an analyst, or a still longer one which occurs if she goes so far as to marry somebody. The married couple are sure to find out a great deal about each other; there is no experience quite like that of marriage for laying bare the personality in all its nakedness.

M: What are the chances of her having a psychotic breakdown?

B: Not yet – but later when she has made more progress. It is something of which she is frightened now, will be very frightened of when it happens, and will also want the analyst to be frightened. What is more, she will mobilize a lot of people to say, "What have you been doing to this beautiful, gifted girl? She was all right till she came to see you." So you have all that coming.

10

Presenter: The patient, a twenty-year-old girl, came in, sat down and said, "Do you know what happened? My phone was disconnected. I went to ask what had happened and they said the account hadn't been paid. They said they would reconnect it. It's not right, is it? Do you think it's right?" Then she said, "Guess what mark I got in the test I took – you must guess – I won't tell you. Maybe you don't want to tell me because you're going to give me a bad mark." She stopped for a moment and then said, "I got nine out of ten."

Bion: Do you want to go on being analysed by the patient? She makes an evocative statement, "You guess – then I shall know who you are. If you say nine is a bad mark, it ought to have been ten, then I shall know that you are the sort of analyst who is like a very bad conscience."

P: I said, "I think you are very worried about the kind of marks you think I am giving you." She agreed: sometimes she says, "Yes"; sometimes she expresses agreement with her eyes; sometimes she smiles. Once in a while I ask her what she is smiling about. She says, "Oh no, it's nonsense."

B: There is something about the way in which you observe her that makes her afraid of what marks she would be given as a result of that examination. "What were you thinking about?" "Oh, nothing in particular; please don't pay any attention." It is always the same reaction: "I didn't say anything. I didn't do anything. I didn't think anything. Don't be an analyst and pay attention and observe me. Everybody gives me nine out of ten; don't you dare give me less."

P: She always asks me questions like a small child. Sometimes I feel that she looks like a small child who wants to know everything she hasn't been told. And sometimes I feel that she asks me the

questions because she doesn't stop to think. Everything she tells me has a question mark.

B: In the *theory* of analysis one is supposed to tell the patient the truth: in *practice* it is much more difficult because one does not know whether the patient is strong enough to hear the truth. Patients are sure that they want to know the answer to the question; what they don't know is that the answer may be very unpleasant. We may be asked, "Is life worth living?" Knowing as much about existence as we do at our age, we might be frightened of telling patients what we know. On the other hand we can be equally frightened of *not* telling them – or our children for that matter – what we know. But it may be important for children to know what real life is like; not the life in story-books, or even in psychoanalytic case histories which are more often like bad novels.

There is no particular reason to doubt this assessment of nine out of ten; it can mean that this girl is intelligent enough to understand what is said to her. So in a sense it puts a bigger burden on you who cannot therefore rely on her being so limited or so stupid that she wouldn't understand what she is not really prepared for. She could learn something prematurely, precociously, before she is in a fit state to tolerate the truth. So you have to sum up very quickly whether the person who is asking the question is robust enough to hear the answer. No amount of books are going to answer that question; we can't read some more Freud to find out. But so long as the patient comes to see the analyst, and the analyst has a chance of seeing and observing that patient, there is always a possibility of finding out what we might dare to pass on.

Melanie Klein said – and I think it is borne out – that at the very experience of birth itself, the full-term foetus feels castrated, mutilated, as if the mother's genitalia cut something off. Severed the umbilical cord? Severed the long-distance sense of smell? One would have to be this patient's analyst to guess, conjecture what the telephonic system is that has been cut off; what the messages are that she can't get. There is nothing wrong with her intelligence – nine out of ten is a good mark – and she may feel that the analyst knows more than she does. One could say that while her *intelligence* is nine out of ten, her *wisdom* is not the same as that of the analyst. Wisdom is a long-distance affair and takes time to develop; it has to be experienced. To put it another way: her tele-phone, her tele-vision is

defective, but she may be intelligent enough to know that she doesn't know the psychoanalytic language, the language her analyst can speak. But she must *feel* – she doesn't *know* – that a psychoanalyst is a helpful person, otherwise why come to analysis? It is another of these imaginative or rational conjectures which have to take the place of facts because she hasn't got far enough to know what the facts are. At present she doesn't know her self, but you may be able to help her to know her self.

Again one wonders: what is the distance between her and her self? How 'tele' is it – whether it is tele-phone or tele-vision? Analysis sounds and reads as if we are concerned with the past. So we are, but our past mistakes, our stupidities, our faults and our crimes are not the whole story – although it is quite useful to know what they are. This girl can know that she also wants to be wise enough to know something about the future. It might be all right to be 'married' to her analyst for a certain length of time, but if she wants to have a husband and children, then the communication has to be even with her unborn children. But that method of communication is cut in much the same way as the umbilical cord is cut; we don't really remember the past, and we can't remember the future because it hasn't happened yet. So a great deal of our present knowledge is conjecture about the past, and conjecture about the future. And yet we do feel that there is a lot to be said for prudence and foresight. Implicit in, "What shall I tell the analyst, and what is the analyst going to tell me?" is, "shall I ever be able to profit by past mistakes? Shall I ever be able to know what I did right? If I could, then perhaps I might foresee the future and make decisions which would show forethought."

M: I have been thinking of what Freud said about phylogenetic inheritance. Do you feel that this is something which can help the patient to develop and to live better in the future? How can we bring this about?

B: According to Freud and others, by psychoanalysis. But in *practice* it is quite a different matter. For example, I had a patient who, as a baby, was asleep with his mother, brothers and sisters when a man entered the room, murdered the mother and all the children, but missed him. We don't know what that baby saw – and it was believed by the foster parents that he knew nothing about it – but the patient who came to me had terrifying nightmares, terrifying impulses to be cruel. One day, for example, he saw a pretty girl in the street, put his

foot out, and 'accidentally' bumped into her. She fell and was badly hurt. He was terrified of what he had done, and terrified that he would go on doing it. What that was all about I don't know, but of course I could guess that it had something to do with this dreadful story. But we don't *know.*

What is the correct procedure? To analyse it and make what is implicit and unconscious, explicit and conscious? Or to forget it? But the theory is that you can't forget what you can't remember, and that you have to remember things, otherwise they fester and grow out of control in the unconscious. But as analysts we are not concerned with *theories*; we are concerned with, "What shall I say to this man?"

11

Presenter: The patient came in, greeted me, and lay down on the couch. Her speech was interspersed with sighs and weeping. She complained that she woke up several times during the night. During the day she is unable to take care of her house; she has to stay in bed most of the time and needs her mother with her all the time to comfort her. Although this calms her down, it has been a cause of worry and annoyance to her husband.

Bion: Do you get the impression that she suffers from insomnia?

P: Yes. During the three years she has been coming to me she has had alternating states of insomnia and sleeping well.

B: I don't know what all these sighs and tears are about, but supposedly the patient is in a state of mind in which people are when they are awake. The fact that a person is what we call 'asleep' could also be described as being 'in a different state of mind'. Patients say they had a dream and did this, that or the other; it is quite useful if we can interpret these 'remains', but suppose the patient doesn't have any dreams. Why does this patient not want to 'go to sleep'? Where does she go? And where does she go when she apparently sleeps well?

P: She continued with her complaints, telling me that her husband wants her to look after the house without her mother's interference. I pointed out that her mother's presence had not resolved her feelings of despair and abandonment. I said, "I think your despair is based on the need to know what this despair is about."

B: This crops up with some frequency. It is quite often necessary to point out to patients that they can have feelings of despair about despair, and they can be very angry about it. Putting it as a more general principle: patients hate having feelings at all; whether

they are feelings of anger or despair or depression, they are all hated. They would like the analyst to 'cure' them or make them incapable of having feelings.

P: She changed her position on the couch and sat up facing me. She said that during the morning she hadn't wanted to come to the session because she was feeling very low. She had heard news on the radio that frightened her: the death of a young boy, the son of a politician, in a car accident. She phoned a friend, who had already heard the news, to talk about the accident. She gradually calmed down and then decided to come to the session.

B: Analysis, like other facilities such as the radio and telephone, can make it possible to hear things that could not otherwise be heard. But as a result of being able to stretch our ears with mechanical instruments, what we hear may not be at all pleasant. In analysis, patients are likely to become aware of things they didn't know before; the analyst can enable them to see more and to know more. But that doesn't mean to say that what they can see more of is nicer – it may be nastier. Why does this patient come for analysis? Is she hoping to hear nice things? Or has she changed? Has she begun to be able to hear nasty things? It seems to me that from your point of view the fact that she decided to come again is quite an important indication. It is so easy to feel that if the patient gives up analysis we have failed. Well, maybe – we don't want to dismiss that idea because we can never be such good analysts that we don't make plenty of mistakes. If this patient dares to come again, although analysis is probably as unpleasant as it has always been, it could be an interesting sign of what sort of progress she is making.

P: I said, "I think you came back to find out with me the reason for the mental disasters you have suffered and which you think are irrevocable." She said, "It's true", and then fell silent and became increasingly anxious.

B: I have the impression that she is surprised to find that she helps you by telling you when you are right. But the discovery that she is capable of cooperating with you is very frightening.

P: She said, "On my way here I was thinking about the friend with whom I discussed the accident. She is a good friend because she is always receptive, but I feel inferior because I realize I need her help. It may be because I always want to be the one who is superior." I said, "You came today to make sure that I had not been destroyed by your

phantasies of wishing me ill and wanting to destroy our relationship. You are afraid that you may have destroyed me internally just at the time when you have the most need of my help." She calmed down and said, "This is the vital point. But I still don't know if I shall be able to bear to go on coming to analysis." The session ended there.

Shortly after this a patient who comes four times a week telephoned to say that she was going on a trip and would miss a week's sessions. She added that she was going to look for other psychiatric treatment so that she could get some lithium she wanted.

B: There are always plenty of things to do besides analysis. And if you don't give the patient drugs, there is no difficulty whatsoever in getting them from someone else. The same thing applies to interpretations which can be a drug; if she can't get the kind of interpretations that she likes, she can always get them from another analyst.

Your difficulty is to know what you did wrong. But it is also important to know what you did right. Giving the right interpretation can lead to the termination of analysis just as well as the wrong one. So if this patient finds somebody else whom she prefers, she too may discover that she has made a mistake.

It is very difficult to assess the analytic association. It is easy to be misled by wanting to forget our mistakes, but it is equally easy to be mistaken by assuming that we are going to make mistakes. The analytic experience is a disciplined and unpleasant one – neither the analyst nor the analysand can do what they like. There are masses of seductive alternatives, but the job of analysis is a tough one. This helps to explain why analysts *must* have rests, *must* have some kind of life other than the analytic one. It is very unsatisfactory if they make their home life into a kind of psychoanalysis. It seems to me that analysts often fail to recognize that analysis is a very good thing for analysts – if that is what they want. But if they want a family, then they don't want a kind of psychoanalytic museum. It is extremely easy for them to start interpreting their husbands' or wives' remarks. I think it is a great mistake.

12

Presenter: The patient has been in analysis with me for two years. In an interview before the analysis began, she told me that she had chosen me because she liked what she had heard me say at a conference. She said she was coming for analysis because her husband had problems and she thought that perhaps she could help him to start analysis too. I suggested that it might be interesting for her to work in some way other than psychoanalysis.

She returned for a second interview and spoke in a very incisive tone of voice. "I know I need an analysis for my own work." After a long pause she said, in a different tone of voice, "I know I am very fat." I agreed to start analysis and a schedule was arranged.

She had great difficulty in tolerating any hostile feelings towards me. The things she talked about seemed to belong in fairy-tales; she described her wedding, her wedding dress – everything was so beautiful. She said, "It will soon be Christmas and my husband is going to dress up as Santa Claus – I almost believe he *is* Santa Claus. After all, I believed in him for a long time." Everything was beautiful, her whole life was beautiful. Nevertheless she suddenly said, "You are bad; you make me say things I don't want to say. You're like the witch in the fairy-tale who forced people to speak."

Bion: If she thinks that, why does she come to see you? Alternatively, if she comes to see you, why does she say you are bad? A tremendous number of people have learnt what they think are the sort of things that analysts want to hear. It is an increasing difficulty for us.

P: She reports dreams in that way, as if she is giving me something I would like to listen to.

B: She can dress up in any kind of clothes, or in any state of

mind. The character she chooses to wear can hide her from herself. It is easy for her to feel that both she and you are dressed up, but who the two real people are, in the same room at the same time, is quite another problem.

P: It is as if she offers me a wardrobe and we both have to choose different costumes. At present there is a great deal of confusion. For example, after I made an interpretation along these lines, and after a long silence, she spoke with considerable emotion but the words she used could be found in textbooks.

B: The glimpse of confusion that you get is very important – it is nearer to the 'real thing'. Confusion is a nasty feeling, so patients always want to get the analyst to behave as if he or she knew all the answers.

P: There is something of this pressure in my always feeling compelled to add to the interpretation I have already given, or to give another interpretation seen from a different point of view. There are times when it is very difficult to form a working relationship; she either quickly agrees with everything I say, or she thinks what I say is an accusation.

Sometimes I feel that some emotion is surfacing, although the words she uses are standard textbook ones. Once, when I had pointed this out to her, she said, "Decipher me or I will devour you." I get the impression of cultural poverty; I am therefore very surprised when she shows a knowledge of literature or refers to trips to Europe and the USA.

B: It now becomes much clearer that this is all part of the costume, part of the culture she wears to disguise the poverty of her personality. If you are able to see the person without all this costumery, all the states of mind she has assumed to cover up her poverty, she is not going to like it.

Suppose this patient came to you with a physical complaint: she might be able to put up with the request to take off her clothes for a physical examination. Some patients *like* doing this. In analysis, patients may get a secret pleasure out of analytic examination, the fact that they are stripped naked, and you think they are going to go on coming for ever. On the other hand, the analytic experience may become so frustrating that patients learn to like being frustrated. So – they can like being flattered; they can like being insulted; they can like being frustrated.

I think that whatever you say to this patient there will almost immediately be a reaction. The problem is to see what the reaction is.

P: I am reminded of something that illustrated the fear she felt. She said, "A friend of a friend of a friend of mine told me that she had had a baby in an elevator without any previous warning. This seems unbelievable – just imagine if something like that could really happen, that something could go in or come out without one's knowing it."

B: This is a very important statement. Patients come to analysis but don't believe it has any effect. So it can be very frightening and unbelievable if in fact it works, if there is a result of analytic verbal intercourse. This patient can be afraid of being pregnant, of having a kind of mental baby; and afraid that you likewise would not know what to do. There would be two people in this elevator who would be taken by surprise.

P: She said, "I read in a magazine that in China people don't have any sexual education – young girls are afraid of getting pregnant even in swimming pools." After a short interval she said, in a voice showing more emotion, "Those girls gained knowledge and lost fear simply by talking about it."

B: What we call a 'sexual relationship' has hardly any meaning – it is borrowed from anatomy and biology. But a girl can feel that a certain type of conversation can have serious consequences. If a brother and sister play 'Mothers and Fathers', the attitude of each to that same game is very different. Sometimes both of them get frightened, stop playing, and ask the mother or father, "What shall we do now?" They don't know why they stopped playing or why they want somebody to tell them to do something else.

In the psychoanalytic game plenty of people are taken by surprise, are frightened, and frightened of being frightened of playing this rather dull, conversational game.

13

Presenter: The patient started analysis with me three years ago when he was twenty years old; he was a second-year medical student and had failed his anatomy examination. He complained of anxiety. His parents are Jewish: he says he doesn't feel like a Jew but accepts that he is because people tell him so. But he doesn't follow the Jewish religion.

Bion: How does he know that he doesn't feel like a Jew? What does a Jew feel like? If you say, "I don't feel like a well person", it means that you must know what it feels like to be a well person. If I were told, "I don't feel like a Jew", by this patient, I should feel suspicious about it. It must in fact be that he doesn't want anybody to know he is a Jew. In a sense it is like saying, "I don't feel like a Jew; I feel superior to a Jew."

In any choice whatever, you are bound to choose what you are *not* choosing. To quote an Arabian poet (recalled by Lawrence of Arabia), "For Lord I was free of all thy flowers, but I chose the world's sad roses, And that is why my feet are torn and mine eyes are blind with sweat." The Arabian style of poetry and the Arabian discipline get nearer to what I am drawing attention to. At some point these various choices are made: instead of "all thy flowers" I could say, "all the options"; we cut down the number of options to the number of things that we choose; but we also choose *not* to choose the rest.

This patient chooses *not* to be a Jew. It is a matter of some importance if he chooses not to be one of his parents' children; and if he feels, "I don't want to be like my father and mother", it is more serious still because it means, "I don't want to be like my father or my father's father before that." That is a repudiation of his ancestry. So with what is apparently a simple statement, probably made at a time

when he didn't know very much – he might not even know that the Jews have a very ancient culture and history but just chooses not to be one of these inferior creatures – he has wiped out thousands of years of the history of his race.

This is all conjectural of course, what I mean by 'imaginative conjecture', what I want to include as part of scientific thought. That doesn't mean that I don't want to know some more about this patient, but it seems to me to help map out an area which we might populate with ideas or knowledge.

Have we any idea of what this patient wants to know instead of himself? What area of himself does he want to know nothing about? Falling back on 'rational conjecture', a rational psychoanalytic theory, he could be said not to want to know anything at all about sex, because genetically he must have both a father and a mother, and they may be Jewish. It doesn't tell us very much because we don't know what 'Jewish' fathers and mothers are; it is no good looking up 'Jewish', and 'father', and 'mother' in the dictionary. There is no way of answering this question except by *observing* this personality that has come into the room.

P: I have observed that he is very hostile to his parents. Sometimes he makes comments like, "My mother is a really crazy woman – the only thing she can do is to interfere in my life." And, "My father is a weakling and is often away." When he first came to analysis and had failed his examination, he was having difficulties in relationships with his fellow students. His feeling of inferiority was associated with what he felt was his parents' poverty – both financial and cultural.

B: I can imagine a situation in which, having decided not to feel like a Jew, he at the same time loses his ability to be tolerant and achieves an ability to be bigoted and selective; he achieves a whole area of 'not to be'. We could say that only a fraction of himself is left, and there is a vast area which he cannot learn about because it is inferior. And now he is supposed to pass an examination. It is hardly surprising that he fails if he is engaged in saying, "I don't know this; I don't know that; I don't know the other – it's inferior." How is it possible for him to know himself? To know himself involves knowing his 'self', his 'breed'. Not to know his breed involves a repudiation of breeding.

The analyst is like a person who is turning the pages of a book rather idly. The analysand can say, "Page thirty", or to put it in

different words, "I'm thirty". The analyst is then listening to the story of the book which is open at age thirty. As the patient reads the story of his life, starting at page thirty, can you imagine what happened on pages one to twenty-nine? Can you imagine what will happen on pages thirty-one to forty? These things we call interpretations are really 'imaginative conjectures' about the missing pages. *This* patient has already torn out a whole number of pages – all the Jewish ones. How are we to read this story? How is he to pass the analytic examination if he says to the analyst something analogous to saying to a physician, "I have a pain – oh no, I don't want to take off my clothes – no, I don't want to have an X-ray – no, I don't want a blood test." We try to make the analytic examination as easy as possible for patients and also for ourselves. So you could *feel* – I don't suggest you *say* – "I'll have to know more about this patient; I'll arrange to see him tomorrow, and tomorrow, and tomorrow."

As Shakespeare puts it: "To-morrow, and to-morrow, and to-morrow, / Creeps in this petty pace from day to day, / To the last syllable of recorded time; / And all our yesterdays have lighted fools / The way to dusty death." This patient's yesterdays, his tomorrows which creep at a petty pace, are in fact all over very quickly – the time between 0 and the day of his death; we don't know how many pages there are to the book. So the patient and the analyst don't know at what metronome speed – borrowing a musical term – the analysis should be conducted.

14

Presenter: The patient is forty-six years old. He has three older brothers and two younger sisters. His father was a powerful, wealthy man who died a few years ago. The patient's difficulties go back to early childhood. His testicles remained in the abdominal cavity and two surgical operations were unsuccessful; consequently he is sterile. He didn't finish high-school education and has never had a steady job. His brothers work in the family business, but because his relationship with his father was so bad it was impossible for the patient to enter the business also. He described his father as a violent dictator. The patient left home and lived in a slum for four years. He took to drink and gave his money away to any new acquaintance.

When he started analysis three years ago he was drinking heavily, had hallucinations at night, and was very anxious about the possible death of his father who was very ill.

The first year of treatment was confused: he missed many sessions, drank a lot, and sometimes phoned to say he wanted to come to the session but was too afraid. He made the analytic work very difficult by lying all the time.

In the second year, after his father's death, he changed completely. He became apathetic, stopped drinking and came to the sessions accompanied by his mother. He usually started by saying, "Doctor, I am on foot – I haven't anything to say."

Member: For how long did he come with his mother?

P: Every day for a year.

Bion: Whose idea was it that his mother should come?

P: The family's, because he missed so many sessions and was apathetic.

B: Why did he miss the sessions? Because he didn't come or

because he didn't listen? Or because his mother brought him – not his own legs and feet? If the mother insists on bringing him, not when he is four or six but forty-six, *she* comes to the session.

P: During the second year I felt the analysis was empty. Month after month: "I am on foot." Silence. And a phantasy about having won a football pool, and what he would do with the money – he would buy a large apartment, have a lot of cars, and so on. These were the only communications, month after month.

B: Who is this who says he is going to win the pools? Put it like this: X is betting on the pools; X is expecting to win; if X wins, X is going to . . . Who is X? Of the two people in the room, is it the patient? Or does he think that the analyst is the person who is betting on psychoanalysis and hoping that he will make enough money never to have to do any more work? Who is this person who would choose not to do any work? Is it his mother? Is she betting on having a son who will support her for life? Then she would never have to do any more work and would be looked after and protected.

Having posed all these questions, you can send your senses back to get more information. You have to listen again tomorrow, listen day after day to the patient saying the same phrases – *apparently.* But they are not the same. If he says them today, they are not the same as yesterday; if he says them tomorrow, they are not the same as today; if he said them at age four, they are not the same as when he says them at age forty-six. There is something wrong with the story. It would be all right if he were a four-year-old, or even a six-year-old, but not a forty-six-year-old. Your eyes may tell you that this patient is forty-six; your ears may tell you something else.

It is possible that he *has* to go on repeating – apparently – the same words. I once had a patient who for months on end said, "I don't know what I mean."

P: What was surprising were the changes in him. In the first year he was one kind of person; in the second, completely different; and in the third year he became completely different again. He started talking, and referred to his behaviour during the second year as that of a robot.

B: Sooner or later this patient has to walk on his own feet – not his mother's. Socrates said he was a midwife; he attended the birth of a mind. The same thing applies to us; we can help a patient to get born, to emerge from the womb of thought.

15

Presenter: The patient is an eighteen-year-old girl who has been in analysis with me for five years, four times a week.

She came in, lay on the couch, and was silent for a while. Then she said, "While I was silent I kept wondering whether I was going to speak or not. I thought the couch was hot. And I thought it would be very difficult for you to separate one person from another."

Bion: Patients often do this. I find that it is important to draw their attention to the fact that they are putting distance between themselves and themselves. This patient says, "I wonder what I am going to say." It might be useful to reply, "Well, what is the result of your wondering?"

P: She continued, "As a test I stayed silent to see what would happen." I had the feeling that she was not sure if I could distinguish one patient from another.

B: You could say, "Well, I'll remain silent too, and then there will be two of us who can wait to see what happens." This suggests that there are three people present – she, herself and somebody who is neither of these. So if any two of these could get together, they might hear what one of them alone could not.

P: Might that not imply, "I can also provoke and tease you"?

B: Possibly. That is why we have to be careful with the tone of voice, the inflection and so on. There is not only the difficulty of having to give an interpretation, but also *how* we give it, what musical accompaniment we put to the words.

P: I told her that I thought she was wanting to force me to speak. She answered, "I wanted to know if you were thinking of another patient." I felt that she was afraid of being mixed up with all the other patients, like the children of a very big family who fear that the parents

won't be able to distinguish one child from another. I suggested that she was confused about her own identity. After a while she said, "I have never thought about it." And then, in an anxious tone of voice, "I think I am afraid of losing myself from myself. It upsets me terribly."

B: It may be true that she has 'never thought about it', so thinking can bring with it all the surprise and anxiety of a completely unfamiliar experience.

P: She was silent for a while as if she was thinking about something. Then she said, "Are you saying that I don't understand the words I use? Do you think I use you too much as a sort of reference?"

B: It is curious. Why can't she talk to you? As the analyst I would not object to being 'used', but I would wonder why the patient could not talk to me. Is the practice of analysis making people lose the capacity for ordinary human intercourse? I can see that there is a lot to be said for analysis if that is what you want, or if you want to be an analyst, but not if it is going to take the place of other activities. I would rather play chess, or tennis, or piano duets than be in a state in which I was simply restricted to the very narrow sort of conversation which is psychoanalysis. I don't think one wants to be less, but more of a human being as a result of analysis. But this patient is talking as if she is unable to have an ordinary conversation.

P: It is true that the patient and I very often have great difficulty in establishing normal conversation.

M: Does the analytic relationship form an obstacle to other kinds of contact outside the consulting room?

B: No, but it does put restrictions on behaviour *inside* the consulting room. Although the conversation sounds like an ordinary one, because we use ordinary words, we ought to use those words very carefully. A surgeon cannot use any old knife to make an incision in the skin of a patient; a surgical operation must be carried out in a disciplined and precise manner. Both in analysis, and here and now in what we call a supervision, I use ordinary English because it is the language I know best. But I nevertheless consider that there is a certain discipline which is proper to both these situations. It is alarming to hear two married people, both of whom are analysts, talking as if they were analysing each other. Good gracious! Haven't they anything better to do? They could discuss painting, music, all sorts of things. They could even have a sexual relationship. If the analytic relationship is made into a substitute for other activities, that seems

to be a serious and dangerous by-product of analysis. I have no objection to having the analytic experience which makes it possible for me to take up the analytic profession; I want to be a psychoanalyst. But I do not want that experience to make it impossible for me to have a life worth living where I could never go to the theatre or a picture gallery, or paint or swim.

M: Patients cannot have any social contact with their analysts. What are your views about this?

B: Analysis does make the social relationship more difficult. If, for example, you were a surgeon and your son or daughter fell ill, I don't think you would like to operate on your blood relation; it would be sure to arouse very powerful feelings. That kind of emotional experience would interfere with the necessary clear thinking and destroy your dispassionate technical ability. Similarly in analysis; if you begin to have feelings of love for a patient, that interferes with the analytic relationship and the capacity to think in a dispassionate manner. The analyst should remain under a discipline and refrain from letting down the barriers and having a rhapsodic response – that is, throwing his arms round the patient and having a passionate love affair. That is just as bad as saying, "You don't want an analysis – all you need is to get married." That is nonsense. If you are dealing with a patient who is suffering mental pain, then it is silly to say, "All you need is a holiday by the sea", or, "All you need is a nice man or woman to marry." That is not a cure – marriage is for something else. It is not supposed to be a cure for neurosis or psychosis. But analysis *is* supposed to be.

16

Presenter: The patient lay down on the couch and started to talk. "Mrs J is the owner of the house where I live. She is eighty-eight years old. I dreamt that she was walking along the road, talking about the rental agreement." Then she started shouting, "What are you doing there behind me? Tell me *immediately*. You are a dishonest liar!" This took me by surprise.

Bion: I wonder what the difficulty is. If she knows that you are a dishonest liar, then obviously you would be telling lies behind her back. At the same time, why ask you what you are doing behind her back? Presumably you will only tell her more lies. Alternatively, is she afraid that you do *not* tell lies? If she thinks there is a chance that you speak the truth, that would explain why she asks you what you are doing. To put it another way: there is something wrong with this story; either the patient is lying, or she is slandering the analyst. Otherwise why should she spend her time with a dishonest liar?

P: I said, "I am listening." She replied, "Yes, that's important." She calmed down and continued describing her dream.

B: That is a very interesting sequel. Notice that the analyst didn't start an argument about whether or not he is a liar; he didn't get up and leave the room; he didn't lose his temper. The effect on the patient seems to have been quite helpful. It is not a cure, but a little bit of a cure; it is enough of a cure to make another minute or two possible. Not only does it matter what you say or do; it also matters what you do not say or do.

P: She continued to describe her dream: "Mrs J wanted to come into the house and look it over. There was a portrait of a nude in one of the rooms and I knew that she would not like that. So I tried to

stop her coming into the house, but I couldn't. In the kitchen there were two blood-stained garments."

B: The patient said this was a dream. Did you believe her? It sounds very likely that she wanted to stop you from seeing what was in her mind, leaving her feeling naked. But she wasn't able to lock the door; she wasn't able to make you leave; she wasn't able to put a stop to the analysis right away. So now you may find out what kind of person she is. However, there is always a safeguard: if you give an interpretation she can say, "It doesn't matter – I don't really think like that – it was only a dream."

P: She went on, "I was afraid the house-owner wouldn't renew the contract, complaining that I didn't take care of the house – although it was in an even worse condition when I first rented it. With a magic wand she turned the nude portrait into a Negro woman dressed in a rose-coloured dress. The Negro woman started to move. I saw a door I had never seen before, opened it, and found a dying plant. I was afraid the owner would be angry because I hadn't taken care of it. I tried to revive it with the magic spell she had used, but couldn't." Then she began to shout again, "What are you doing there? You are a liar. You are doing something you don't want to tell me about. I hate you. I want to destroy you, tear you into pieces and throw the pieces away." She was very, very angry.

B: What are you doing to her? She has continued to talk, so she is taking off her own disguises. If you take off the black skin, there is a person there; if you take off the dream, she herself is there. I think she is worried about what you are doing to her. Why do you make her speak the truth? It seems that you are only talking, but she knows it isn't only that. You are talking in some peculiar way which makes her expose the truth. This analytic conversation is very disturbing and frightening to the patient; she doesn't know what will appear. She is frightened of you because you don't only hear what she says, but understand what you hear; and she is frightened of herself for coming to see you. When she is so angry that she hurls these accusations at you, it also means that she is very frightened – being frightened and being angry are so nearly the same thing; they are feelings which are fundamental; they could be felt even by an embryo – in medical terms, the development of the adrenals. These fundamental, primordial feelings of fright, anger and hate are seeping up so that the patient cannot think clearly. So it would seem to be quite a good idea

to make the analyst frightened and angry too: let's start by calling him a dishonest liar and see if that will frighten him or make him so angry that he won't be able to think. Then it will be all right because he won't be able to think any better than she can. But we know it is no use at all to have *two* people in the room who can't think. So although it is horrible for the patient, it is just as well for the analyst to remain able to think. But we cannot settle this matter by being unable to be angry or frightened; we have to be able to have these strong feelings *and* be able to go on thinking clearly even when we have them.

17

Presenter: The patient is a fourteen-year-old boy. He came in and lay down on his front – not in the usual position. He began by saying, "If you were ill next time, we shouldn't be able to have our session and I would save money." Then he looked at me and said, "You are moving your fingers." He kept glancing at me all the time. Then he asked, referring to a boy who he knew had been one of my patients, "Did he leave you?" Then, "How long does an analysis take? Is it possible that I shall be here for ten years?"

Bion: I might say something like this: "You are not really sure whether you are the boy who came here and never came back again, or whether you are the boy who came here and has come here again today. But since you are the boy who has come here today, you are beginning to be afraid that you might also be coming here for ten years. And you would like me to be able to tell you how many years you have been coming so far, and how many more years you are going to come."

I suggest that this boy feels he has already been coming for fourteen years – in fact ever since he was born – and that it's quite long enough. At the same time he is not quite a boy – he's a young man; and he's not quite a young man – he's a boy who needs a father or mother or psychoanalyst to come to. In short, we are looking, at rather close quarters, at what is known as an adolescent. It's no good telling him that because it wouldn't mean anything to him. But he could possibly understand if one said, "You are feeling like a grown man and you are tired of being a boy. But you are frightened of being a grown man and would like to be a boy for a bit longer – perhaps for ten years more. You want me to tell you when you will be a man and when you can stop being a boy."

These are just rational guesses, rational conjectures. But during analysis you don't have time to discuss this kind of thing. Here we can imagine that the patient is waiting for the interpretation, but in real life he wants an answer straight off. This is the analyst's problem: how to answer on the spur of the moment – literally, for the moment is a spur which is provoking an answer – and how to give an answer which helps the analysis to go on but which isn't too much or too little. This is why treating adolescents is so difficult.

To give a pictorial image: if you are the captain of a sailing ship on a stormy sea, you have to know *at once* what sails to carry or what sails to strike. That is why the experienced captain has an advantage; he doesn't have to think too much because he has done the thinking beforehand. In the same way we have this kind of discussion so that we can do our thinking before we have to answer; it is useful to keep our own imaginative and rational conjectures up on the surface, ready in case we want to use them.

P: He got up from the couch and asked me, "Don't you want to give me the small box?" This contains things for drawing and painting which he used when he first came to me at the age of twelve.

B: "Can't I be a little boy a little longer please?" He doesn't want to grow up just yet.

P: He began to draw a copy of the cheque he had brought for the monthly account, saying that if he were the analyst he would keep the cheque for himself. He spent the rest of the session drawing the cheque – a very exact likeness. Then he tore it up and, indicating the real cheque, said, "I'll take this with me." He looked at me, took the torn-up drawing and left the cheque.

B: You are dealing here with an emotional storm, a dynamic situation. So whatever you do will probably be wrong the next moment – or possibly right. That is the problem with having to reply instantaneously in a situation which is constantly changing like the waves of the ocean.

M: Perhaps he was drawing the cheque because he isn't able to earn money and write real cheques.

B: When will he be grown-up enough to write cheques of his own, and when will his own cheques be worth as much as those of grown-up people? If he could write the cheques himself, perhaps that would pay him.

M: He may be identifying with his father, drawing the cheque in competition with his father.

B: Yes, but his pencil, his penis, isn't a very potent one. Cheques which his pencil or penis can make are not as powerful as the cheques made by his father's pencil or penis – or the analyst's. He is at this awkward stage where he is not a boy or a father; he is both of them at the same time.

P: I felt that he wanted me to impose limits on him.

B: It is perfectly true that he may want you to do that, but he also wants to be free. So how are there to be limitations which mustn't be limitations? I find the pictorial image of the storm-tossed sea useful, the motto of the city of Paris: '*fluctuat nec murgitur*'; storm-tossed but not submerged. This boy is saying, "How high are these waves going to rise? How high are these emotional feelings going to rise? What are their limits? But there mustn't be any limits – I don't want them to become a prison."

18

Presenter: The patient is a woman journalist. She came twenty minutes late to the session I am reporting, did not use the couch, and sat in the chair. On some days she uses the couch, on others she sits in the chair; sometimes she changes places during the session. She arrived looking tired, as if she had been running, but she was well-groomed and well made up. She said, "I wish I had come earlier because I would like a rabbit to come out of my hat today. Lots of things have happened: my mother is going back to the States, and my sister is getting divorced. I have been thinking about leaving analysis because my sister will need money for the divorce. I have other problems as well." After a pause I asked her what she meant by 'other problems'. She said she didn't know, but she thought she should stop the analysis because she didn't deserve to have so much money spent on her; she should move to a little house in the suburbs instead of living in several houses.

Bion: I get the impression that she has become aware of the fact that there are an enormous number of options. The problem is, how is she to spend the limited time and money she has? And because they are limited it matters very much what she buys. She could spend the money on a divorce for her sister. Or she could spend it on herself. But it sounds as if she would be unable to tolerate her guilt if she spent her resources of time and money on herself.

I don't think I would say any of that at the moment because I am not sure that she could stand it. I would probably want to hear some more. In the meantime I would keep to myself the opinion that this is a fundamental, basic guilt, the kind of conscience that, if one took a religious view, one would call 'original sin'. But from my point of view these are symptoms of a very dangerous conscience which is

more of a liability than an asset. It doesn't tell the patient what to do; it only tells her what she must not do. So I suspect she is afraid that you are that kind of conscience.

If I were the analyst, what interpretation should I give the patient? Or should I remain silent? If I remain silent, I am slipping into the position of being the conscience who is no good to her. I need more information and would therefore prefer to remain silent until I hear some more. But I would not know whether I could afford to wait or whether it would make her more than ever frightened of me as the unhelpful, hostile conscience. On the other hand, if I gave her that interpretation I would be afraid that it was premature. In either case there is a risk that she will walk out and not come back. Could I say something that would be neither of those mistakes?

P: Perhaps I might say, "How about looking inside this hat you mention, and trying to see those rabbits?"

B: The danger I would anticipate with that would be of the patient thinking I was being frivolous or taking her statement seriously. I don't say that is necessarily an objection to it; I think there would be an objection to whatever you said or did.

P: I got the impression that she was bringing a divorce upon herself.

B: Divorce, like marriage, is only an institution. The question is what does one use either of them for, and why one rather than the other? Why does this patient think that divorce is the best present she can give her sister?

I would be inclined to draw her attention to the fact that there are actually two people in the room, but there is also an observer who is watching this verbal intercourse between you and herself; while she is participating in a conversation with you, she is also listening to it. I might add, "In other words, I think that you and I are being watched by a very inquisitive person who is also you." If that is right we are dealing with something basic. It is reminiscent of the biblical story about curiosity which impels a character to eat of the Tree of Knowledge. This is a dynamic situation involving these three characters – analyst, analysand and observer. But we don't know which is playing which part at any given moment; they are constantly changing. It is also fundamental in the sense that it is called a 'triangular' situation.

P: It occurred to me that she wanted to leave analysis as a way of coping with feelings of abandonment and separation. Her mother is leaving her to take care of her sister, making her feel abandoned, so she will abandon me and leave me alone too.

B: The two are left alone, again with a primitive conscience. I could put it in these terms: two young children need a parent because that parent has a great deal of experience; this primitive conscience has no experience and does not know enough to look after two children. The experienced mother is liable to seem very strict because she is always saying, "Don't do this", "Don't do that", "Don't be naughty", and so on ad infinitum. But in fact the experienced mother is much milder, much less severe than the inexperienced conscience. So the danger of leaving two young children alone is not only all the naughty, bad things that they would do, but because they would be at the mercy of a very severe, harsh and inexperienced conscience. At a much later stage the danger in that kind of moral system is that it can impose a sentence of death unnecessarily; in other words, it is the sort of conscience that can drive a patient to suicide.

Although we are dealing with this in terms of childhood, we are in fact dealing with something which would be very serious if it were left untreated. This is what makes the analytic experience so important; patients can be helped to modify their ideas of right and wrong in comparison with what they now know. We do not say, "With a conscience like that, leave it to them to keep themselves dominated by such a conscience for the rest of their lives." The analyst may, like the mother, appear to be very restrictive because he wants patients to behave in a civilized and polite manner, not simply to go straight from some impulse to action without the intervention of a pause for thought. That is one reason why we believe that there is a lot to be said for discussing these matters and thinking about them. You may get a patient who, instead of working it out with the analyst, goes to the United States or England or France – acting first and repenting at leisure. It is a serious situation if a patient telephones to say, "I want to see you Doctor." "All right." "But I can't – I'm in the United States." Instead of spending all these months and years in analysis, the patient goes straight from the impulse to action, doesn't know what to do, and can't get back for the next session. So this patient is actually being quite sensible; she doesn't go to the United States; she comes to see you.

19

Presenter: The patient, a woman, has been in analysis for two years. From the first I had the feeling of being in the presence of an unprotected and defenceless person, although she did not express this verbally. In the session I am reporting she said that she had a phantasy that she came from an egg and that in leaving the egg she hurt herself. She said that before the analysis she lived without being conscious of more than half the things she did to herself. "I had no idea if it would be good to leave the egg or not. I just jumped, and plop! I hurt myself. After starting analysis I tried to leave the egg more carefully. I think you were right to say that unless I want to know the truth, the analysis can't go on. It is like the chicken hatching from the egg; if the chick isn't ready to leave the egg, it could hurt itself by trying to force its way out. I think I shall know when the egg is right. Can you hear me? I feel you are so far away from me that I can't see you."

Bion: You had not left the room; nor had she. So what had happened? The physical senses don't seem to throw any light on this. However, I have a very great deal of respect for what the patient says. What senses is she talking about? Is it possible that she has eye-sight which tells her one story, and in-sight which tells her another?

The baby seems to be aware that it is dependent on something else – something not itself – such as a breast, a bottle, a father, or a mother. It seems also to know when there is nobody else in the room. It is an unpleasant experience, this feeling of being dependent, incomplete, and at the same time the feeling of being all alone. This patient can be aware of being all alone with a psychoanalyst in the same room; she is dependent *and* all alone with the object she depends upon. When she came out of the egg, or her mother's inside, she could experience these feelings but would not then know how to

communicate them; today she can communicate them verbally, but she has forgotten what they are. I say she has 'forgotten' what they are, but as analysts we may have to revise our views about 'forgetting' and 'remembering'. Has this patient 'forgotten' what it feels like to be a new-born baby? Or is she 'remembering' what it feels like? I don't know. These words have so many meanings that they are of no use to us. If we want to make a scientific communication, we shall also have to make a work of art.

P: She said, "I feel the need for sensual contact like the need for oxygen. I need to touch people, to embrace them, to stay close to them. Since I have been in analysis this feeling has increased." I said, "I think you are confused by feeling like a small child, unprotected, defenceless, who only feels safe in close contact with the mother."

B: She might say, "I don't understand all this talk, but if I use my hand I can understand this table, or if I could touch your body, then *my* body would know what *your* body was saying. I don't understand these noises in my ears; let me touch you, and then my hand will understand what yours says." If she cannot stand the situation, she may actually hold your hand. What she doesn't know is that if she does, she will have such powerful feelings that she will get frightened. In fact she could get so frightened that she might never come back again – not because she has been prevented from touching you, but because she has been allowed to. So – what are we to say to a patient who wants physical contact? Or what are you to say if a patient tells you, "I don't understand this, but if you had a piano here, then I could play it and you would understand what I mean. All this talk is no good – I can't talk"? Or perhaps a patient says nothing at all but just gets angrier and angrier, and more and more hostile. At last he says, "Why don't you *do* something?" "Well, why haven't you told me anything?" And the patient replies, "I've done nothing but tell you – I've been telling you for the past two weeks." As far as the analyst is concerned, the patient hasn't said a word; he has come every day, five times a week for about two months without saying a word. But he is furious because he has told the analyst so much, yet the analyst knows nothing of it.

People often fail to realize that besides talking, analysts also listen. I think the patient we have been hearing about knew that the analyst was listening – that is why she said, "You've gone away." She must have known that the analyst was still in the room; something was

there, and she had the intelligence to know that although it couldn't be smelled or touched or felt, the analyst was thinking.

There are cultures which expect people always to be talking, always making a noise, so that anybody who is thinking is assumed to be doing nothing. The analyst has to be able to respect and pay attention to his own intuition while pressure is put on him to say something, or to do something, or to touch the patient, and to give up remaining in silence where he can at least hear himself think.

20

Presenter: The psychiatrist who referred this patient to me diagnosed him as psychotic. He had been committed to hospital. I didn't have a vacancy but I interviewed him and we agreed to leave it until I had a vacancy. Later he left hospital and phoned me, but I still had no vacancy. I said I would phone him when I had a mutually convenient time.

Bion: Where does this idea come from – that the patient needs help? We can understand that the psychiatrist would think so, but the interesting thing is that apparently the patient thinks so too. In other words, he is not so mad that he doesn't know he needs help. There are plenty of people who are what we would call 'insane' but who wouldn't want any help from anybody; they could feel that they were quite all right. But this patient seems at any rate to be sufficiently well to know that he is ill.

P: When he first came he gave the impression that he expected a great deal of me. At the same time he couldn't articulate words to express himself in order to communicate with me. I experienced this problem of mutism with another patient, and based on this I had the impression that this patient would remain silent for a long time. I knew he was studying architecture, so I suggested that he might like to do some drawings for me if he was having difficulty in using words. He accepted the suggestion enthusiastically, and has drawn in every session since.

A kind of ritual has been established: he does the drawing; I ask what he has drawn; he gives it to me; I look at it and ask what he thinks about what he has drawn. Sometimes I ask, "How do you interpret the drawing?" Or, "What have you drawn?" In the last session I said, "Give the drawing a title." He thought for a while

and then answered, "Bestiality Advancing". I asked him, "Are you representing the advance of bestiality by a foot that is advancing?" He replied, "Bestiality is not a foot; it is something that has feet." He spoke quite quickly and then drew a line round the picture as if it were a framed painting. [Hands the drawing to B.]

B: I could say: this is a funny piece of architecture; this looks like a drawing of a part of the anatomy. If that is the case, then perhaps he thinks the human body *is* a piece of architecture; it has a skeleton in much the same way as buildings have – iron girders, ferro-concrete. But *this* building is a plan for one of flesh and blood.

P: This might be the 'bestiality' to which he referred.

B: It is very interesting: this patient, who has been diagnosed (probably quite correctly) as psychotic, is also well enough to know he is ill. That is point number one. Point two: he is also well enough to know that the analyst is likely to help him, so he doesn't mind cooperating by drawing a picture. He doesn't tell you in words where the pain is, but he draws a picture of it.

M: Isn't it dangerous to consider that a drawing of this kind is a mental communication?

B: I think it is dangerous to consider anything. Psychoanalysis is a dangerous occupation; so is being a doctor or a fireman. In all these occupations people lose their lives. And it is just as well to remember that analysis is a dangerous occupation *whatever you do* – if you don't do anything, or if you *do* do anything.

This drawing is *of* something. If it were a house on fire, one could say that the flames were advancing. But if it's a drawing of a piece of human architecture, then it is a state of mind that is advancing – bestiality. In other words, he does not feel that he is becoming more civilized, more polite, more cooperative, but more bestial; not more human but more like the beasts.

While we are dealing with the advance of bestiality *now* – which may have advanced too far already – it would also be useful to know where it started, where its origin was. If we knew that, perhaps we could stop the origin from feeding the advance. If we were dealing with a fire, it would be important to contain that fire to prevent it from spreading. But it would also be important to know what was feeding it. If it was a physical ailment which was advancing, it would be useful to know where the source of the infection was. In fact I think that your asking the patient to draw is helping to contain the spread.

Drawing is quite a civilized procedure; it has a long history; it even goes back to cave paintings twenty thousand years ago. We can see signs in the patient of something which has a long history, is right up-to-date, and we come into the story very late.

21

Presenter: The analysis of this patient seems to have been through three phases. In the first she was chiefly preoccupied with the material conditions around her, such as the couch. She was very rigid about the schedule for sessions and became aggressive if any changes were made. On one occasion I was surprised to find myself twisted in my chair, trying very hard to follow her words because she was speaking so softly. It was only after I noticed this that I realized that she was exercising control to such a degree that I was unable to think analytically.

In the second phase she spoke almost as if she was talking to herself. Later she exhibited the same anxieties about material objects as in the first phase, but in relation to me, saying how nice I was, or how punctual. But I noticed that she was now using her talking as an evacuation so as to avoid contact with me, pushing me away.

In the third phase she began to consider me as a person. This phase was tinged with deep doubt and anxiety; she said she was now able to glimpse another world although she couldn't reach it. She was able at this stage to refer to the importance of analysis in her life.

I am going to describe yesterday's session –

Bion: Before we hear about this session, there is a question I would like to ask. I get the impression that the patient knew you would have to twist round in your chair to hear what she said. Did you feel that she knew you could not hear what she said and that you would have to move your bodily position?

P: I don't think she was consciously aware that she was forcing me to twist in the chair; I only felt it and observed it in myself.

B: If you were only a piece of furniture, a piece of wood, then there would be no question of making you feel anything. But if she

is aware that you are a human being, then she is also aware that you have to listen in order to hear what she is saying. So if she speaks very softly, you will have to do something about hearing what she says. This would certainly fit in with what we have already heard, namely that she is not really aware of you as a human being. But in so far as she *is* aware of that, she will also be aware that she is doing cruel things to you.

Let us hear more now about what happened in yesterday's session. We have heard the historical part: now we expect to get a much closer view.

P: She came into the room, handed me a cheque and said, "Today I am very worried because I put the wrong date on the first cheque I wrote. I'm disturbed." Then she went on to describe how she was nursing her two children who have 'flu. (I was surprised to find that while she was talking I was looking at the cheque and noticed that she had made it out for too large an amount.) She said she felt very happy to be able to look after her children; she had formerly had a maid with whom she used to leave them. I said, "Your disturbance can be seen in the cheque you wrote. You are expressing not your worries about your children, but your maternal feelings, the aspects of being a woman, of your sexuality." She agreed, but said I should also notice that as well as looking after her children she is now able to talk about sexuality to me. She drew my attention to the fact that she is now able to wear dresses whereas she used always to wear trousers.

B: It seems to me that in what you have described as the first phase, the patient didn't really know that you were a live person, or was being cruel to a live person – and to herself to some extent; if you cannot hear what she says, then you cannot give her any interpretations and she cannot get any treatment. However, something happens during this time which makes possible a second phase; both she and you have changed. Similarly with this second phase; something must have happened to make possible a third phase. If she has developed or grown, then she may have grown past the stage of wanting to be cruel to a 'thing', and she can feel indebted to you because you have put up with phases one and two.

It is difficult to know why this kind of psychoanalytic conversation should actually relieve a real mental pain and produce a real cure of a real mental pain. Analysts talk and argue about Kleinian theory, Freudian theory, Abrahamian theory and so on, as if they

had forgotten that behind all these theories there are people who are actually suffering. It is almost like a surgeon regarding an operation as a bit of carpentry carried out on a living body. You would soon see the point if a dentist drilled your teeth and regarded it simply as a technical accomplishment as if he had forgotten that those teeth belonged to a real person.

It is easy to get involved in arguments about technical questions as to who knows the most theories, or the best theories, and to forget altogether that we are concerned with *people.* Paradoxically, we are so close to the suffering, so involved with giving the correct interpretation, carrying out the correct mental operation, and patients are so concerned with how painful the correct mental procedure is, that it is a surprise to find as they progress that they are different; they are what we have to call, 'better', 'healthier', 'more cured'.

This patient discovers that all her past sufferings, anxieties, troubles, lead to a situation where she has a family of her own. It can be a surprise to find that it is quite nice to have children of her own. She may not feel that she remembers how she got there, but she can feel that she owes a debt to you. The problem that now arises is, how is she to express her feelings of gratitude to you? On the face of it she can fall back on the idea of money as a method of settling that debt. But what, if any, payment are you to expect if you are a good analyst? What coin are you to be paid in? There is a saying: virtue is its own reward. The reward for being virtuous is being virtuous; the reward for being a good analyst is being a good analyst; the reward for being a good father or mother is simply being a good father or mother.

22

Presenter: The patient usually arrives a little late, lies on the couch and immediately starts to talk. Yesterday he arrived ten minutes late and paused for about a minute before speaking. He said that while he was silent he was thinking about your lectures. He had considered attending those meetings but was afraid he would meet his former analyst (with whom he had been for eight years) and would not know what to say to him. He said, "It's funny – I remember things people tell me; I remember things about those people; and yet I don't remember the people themselves." He has been in analysis with me for six months, two months of which he spent in Europe. He said that while in Europe he sometimes remembered what I had said to him but never remembered me. He said this also applied to his memory of his father; he remembered his father's words but never his father.

While he was saying this I recalled that he had a habit of using quotations. My interpretation was, "You use words as if they were something that can be kept in a cupboard and which are at your disposal, but you leave people aside." He seemed to agree with my observation. He said that although he is 'intelligent, sensitive and shrewd', he is unable to retain the things he learns. As a result he feels ill at ease even when among friends. He thinks that is why he doesn't enjoy any serious conversation.

Bion: What strikes me about this is that he thinks he knows 'why'. People very often say, "Because . . . because . . ."; then while you are waiting to hear the cause, they don't tell you. This patient tells you the cause, but we don't know that he really knows what it is. If he knows the cause, why bother to tell you? The reason why he tells you is in fact that he does not know. I think he is frightened of you and of what you will find out. In physical medicine this fear can be so great

that someone who thinks he has cancer won't even go to see a doctor. When a patient comes to see an analyst, he hopes that the analyst will say there's nothing the matter. At the same time he is afraid that that isn't true, and also that the analyst will say, "Let's find out."

P: He refers to himself as a 'homosexual' so as to shield himself from any examination of what leads him to consider himself thus.

B: These words are so commonly used that they lose their meaning. I think one has to consider what language the patient is talking; it can sound just like a psychiatrist or a doctor – but it isn't.

P: He told me that on his return from Europe he had accepted an invitation from a girl-friend to spend the week-end at the coast. But since her parents would be there and he would have to converse seriously with them, he didn't go. He preferred to stay in the city with men friends and sit and chat with them. He says he enjoys chatting with men friends because it gives him a chance to feel very witty. The conversations are not serious but require his astuteness and wit.

Ever since childhood he has been surprised by the anxiety he feels when night comes because in fact he enjoys night-time. When he was an adolescent he went out with friends at night because he was afraid to stay at home. He has to go out every night to meet friends, and after these exchanges of witticisms he ends up by choosing a male sexual partner. Although he is not very explicit about it, he implies that he takes an active part in the relationship.

B: It seems to me that he can't stand the fact that you can observe him in daylight. He would like to be able to cover himself in darkness in the way that he can at night-time. If it is daylight and he is in a conscious state of mind, he is uncomfortable – he has a pain which he calls 'anxiety'. It would be much nicer if it were night-time and he could be hidden so that you couldn't see him. But he is afraid that you may be able to see him *and* keep on thinking whether it is day-time or night-time. So he takes refuge in staying awake at night. And while *you* can see men *and* women, he can only see half the human race – that half which looks like him.

P: Two things you say remind me that as a result of an attack of polio the patient limps. One is your mention of night as a refuge; the other is your reference to his only being able to see half the human race. Perhaps he feels only half a man and wants to hide his limp.

B: The difficulty can also be that the unmarried man is only half a human being. One can say that biologically the human unit is a

couple; it takes two human beings to make one. It is simpler if this patient can feel that he is complete because he doesn't want to have to find a mate. In fact he doesn't even like having to find an analyst; although he would like your help, it would be much nicer if you could send him your words but stay away yourself. This incomplete person is having the unpleasant experience of being all alone with himself and with you. If you left him, or he left you, he would have to get another analyst straight away. But he is frightened of a successful analysis, of what he might see if you opened his eyes or his ears, or any of his senses. And he is frightened of an unsuccessful analysis; he's not sure that he wants to remember the past, and he doesn't want to 'remember' the future either.

P: He is an art dealer and has a partner in his business, but would prefer to work just for himself. But he is afraid to do this. He lives with his mother, grandmother, sister and brother. He would like to set up home on his own but cannot.

B: He is not 'at home' with himself. But whether he likes it or not he has to be 'married' to himself for as long as he lives. He objects to being the kind of animal that has to have a mate, but while he may not like being with his analyst, he likes it less still being alone with himself. So since he has to have a mate, the only thing he can choose is another human being – and all human beings are so much alike; they are all imperfect creatures. So then there are *two* imperfect beings and the problem is whether these two halves make one whole or not. Will these two halves fit together? If they are both women, or both men, they don't fit.

23

Presenter: The patient came in looking very tense. She lay on the couch and remained silent. I asked her if she wanted to speak about the subject of payment which she had mentioned in the previous session. She got up from the couch, sat on it, opened her purse and took out an appointment book. She said she didn't think she would be able to pay me until the beginning of next month. I had the impression that she wanted to establish some kind of link, a complicity.

Bion: We can all now say what we would do if we had an experience of the kind that has been sketched out for us. It can't take the place of what the analyst already knows, but we can give our imaginations an airing. I don't want to appear to interfere with what you are talking about because I could call that 'sacred'. What I would do if I had such a patient is more a matter of my peculiar mentality than of the actual analysis. The way that I do analysis is of no importance to anybody excepting myself, but it may give you some idea of how *you* do analysis, and that *is* important.

I don't think I would say anything about the previous reference to payment. But after a time, and if I thought the patient could understand, I would say, "I can understand now what you meant about the difficulty in paying. You are mentally constipated, so you are not able to give me any free associations – you can't give me any information and I can't give you any interpretation. So we can see how difficult this question is: how are you to pay me, and how am I to pay you? There are two people here, but this silence shows that neither of us can pay." If I give that interpretation, then I have the chance of seeing from the patient's reaction whether it seems to be the right one, or whether I have made a mistake.

We know now what in fact you did say to her in the actual situation. So we can go on from there.

P: I told her that I didn't know for whose benefit she was explaining in such detail why she was unable to pay. She became very irritated and said, "Well, you are quite right; next time I'll pay you. As a matter of fact, if I haven't the money for more sessions I can always give up coming here." Then she lay down again and lapsed into silence.

B: Did she say she was irritated, or was it an observation of yours?

P: It was my observation. She is a dancer and uses her body very expressively.

B: That is the kind of thing that makes the analyst's position quite different from any amount of theory. You can use *all* your senses in the analytic session – conscious or unconscious – so that you have a very great deal of information.

Why does this patient not know that you are there to help? And if she doesn't know it, what has she come for? Why is she irritated, annoyed? After all, you have only told her something in order to help her.

P: She remained silent for some time. After a while I felt I could ask, "How can I help you?" She said, "No, you can't help me." I said, "But isn't this a contradiction? You say I can't help you, but you are here." She said, "Well, to avoid the contradiction I had better leave." She sat up, arranged her hair, and left the room with an air of offended dignity.

B: Well, what about that? If she feels disposed to translate her feelings into action and walk out of the room, it might be because *she* can't help *you.* There is nothing she can do for you: you aren't her baby or her husband or her son – or even her patient. However, she has actually created another difficulty because she has gone straight from the impulse of annoyance to action. And if she wants more analysis she will have to come back again. That is much more difficult than it would have been if she had not walked out. You can't do anything about that; you can't bring her back or tell her to come back because that gets close to breaking the law – you aren't allowed to imprison the patient. If you said, "Here, come back!", she could bring an action for damages on the grounds that you weren't

allowing her to be free. She has to learn the hard way, namely that if she translates her impulse into action without thinking, then she has to do more thinking to get back again. Or she will have to find another analyst – which is just as bad.

This can all be very disagreeable for the analyst because none of us likes losing patients; we always wonder what we have done wrong. It is quite useful to know what we have done wrong, but it is also just as well to remember that in this world accidents happen and ordinary human beings make mistakes. We aren't obliged to be God; we aren't obliged to be what we can't be. It is not our privilege to be free of mistakes; it doesn't matter how old or how experienced you are – you will always be making mistakes.

What happened next?

P: She came again the next day.

B: We are always having to stop the story when it is getting very interesting.

24

Presenter: The patient, a woman of twenty-four, has been coming to me for nine sessions. Sometimes she sits on a chair; sometimes she lies on the couch; and sometimes she changes from one to the other during the session. In the session I am reporting she chose to sit on the chair. She said, "I would like you to explain what you said yesterday about my being unable to cope with my feeling of anger." She fell silent, waiting for me to reply.

Bion: I would feel that I had explained it to the best of my ability. If the patient didn't understand what I said yesterday, what is the good of my saying it again today? One says it at the time when it is possible for the patient to know what one is talking about; the next day is a different day, a different situation. Is there any point in acceding to that request? On the other hand, is it a good thing for you to make no reply?

P: I had the impression that she was talking about feeling angry, but I couldn't see or feel any signs of anger while she was with me. I think she wants to talk about the past, while I want to talk about the present. She wants to build a wall around herself with rational words and remain inside that wall with her own feelings. I am somewhat anxious because I cannot put my finger on what she is actually feeling, and I haven't enough material to form an opinion.

B: You are not obliged to talk if you feel you haven't anything to say. Only *you* can know when you have enough evidence to give an interpretation.

P: I felt constrained by her behaviour to understand her feeling. This worried me.

B: This is typical of the way in which pressure can be put upon you by the patient: a demand for premature or precocious reassurance. But you have to be able to resist these demands.

M: I wonder why we feel compelled to give interpretations. If we have only been seeing a patient for a short time – as with this patient – we cannot give a profound interpretation.

B: It is usually because we are afraid of losing the patient. At the beginning of an analyst's career he is afraid that supervisors or training committees will count it against him if he loses patients. I think that is nonsense. If I were on a training committee – as I have been – I would consider that those patients had certainly taught the analyst something about what it feels like to lose a patient.

With a new patient it is of course useful to fall back on a certain amount of psychoanalytic theory when there is very little else to go on; it is useful for about three sessions. Giving interpretations after that without the necessary information encourages the patient to think that the analyst doesn't need evidence.

P: The patient said she felt very sleepy and relaxed as if after massage. She then found a comfortable position in the chair and fell asleep. I thought she might sleep until the end of the session and I would then have to wake her.

B: I have known a patient come forty-five minutes late for a fifty-minute session. He lies on the couch and says one or two sentences; I get up and say, "We've finished." "That", says the patient, "was a very short session." I suspect that the patient is not aware that time passes. If a patient is wealthy enough he can use the time however he wishes; as well as plenty of money, he thinks he has plenty of time. But how does he know that? We know that we can die at any time – even before birth. So why does this patient, at twenty-four, think that she has plenty of time, and spends it sleeping?

There is another question: why does this patient feel safe enough with you to go to sleep? If she were my patient I would think, "She doesn't know who I am; she has only seen me nine times; why does she think it safe to go to sleep with a stranger like myself?" Either she is desperately short of sleep, or she has a completely mistaken idea of the safety of going to sleep in the presence of a stranger. One is bound to wonder, what is this sleep? Is it a form of catalepsy? . . .

25

Presenter: The patient is thirty-two years old, a paediatrician, and comes from the north of Brazil. His father is violent; his mother was sickly and died when he was seven. His is a big family. As is usual in the north, one of the children was chosen to study for the priesthood, and he was that one. He left the church school in a state of revolt, was able to pay to study medicine, and became a paediatrician. While he was still living in the north he made three suicide attempts: twice by poison and once by shooting. He came here two years ago, got married, and has a baby daughter.

He first came to me three days before my vacation was due to begin, having already cancelled an arranged consultation. I had the impression that he was afraid of coming, and during the interview I understood why. He told me that when he was a little boy he returned home after a vacation and found that his mother had died. As I was due to go on vacation I think he was afraid of establishing contact with me and then being left alone. He wanted to be quite sure which day I would be back and when I would be able to see him again.

Bion: Don't you think it is very significant that although he has all the drugs of a pharmacopoeia at his disposal, he can't poison himself properly? When he has a gun, he can't even shoot himself. So he's a bungler. What reason would he have for supposing he would be any good at anything? If there is something that *anybody* ought to be able to do, it is to kill themselves – there isn't even any opposition – there is nothing between him and the person he wants to murder. So if this patient can't even murder himself, what do you think he *could* do?

P: What he can do is to blackmail.

B: One wonders if he would be any good at that either. On what grounds does he think that he can bring up a family? Why does he

think he can support a family? I am not suggesting that you can say any of these things to the patient, but I think we can consider them here. Do you consider that such a person would make a good, capable, potent husband? These questions raise a surprising problem: somehow he has persuaded somebody that he would make a capable paediatrician.

P: Perhaps in the same way as someone thought he would make a good priest, or as someone has persuaded him to undergo psychoanalytic treatment.

B: Does he always do what he is told? As a boy he may not have been in a position to refuse to go to school, but he set himself up against the authorities in his revolt against entering the church. Although he could be qualified as a priest, he knew he couldn't *be* one.

P: He apparently acquiesces in what is asked of him, but internally he is full of hate for his family, for me, for everyone including himself.

B: But he is still unable to kill himself. Even if he couldn't kill his father and mother, one would still think that, hating himself, he could kill himself – but he couldn't.

P: He said, "Nevertheless, I need you. I would like to be resting inside you. But I am afraid someone would come inside me." When I pointed out that he wanted to identify with me, he became frightened and said, "I love you."

B: I wonder why he thinks so. He has talked about two fundamental things: hate and love. All other feelings are really variations of love and hate; it is easy to learn the words; if you can read, you can find them in any dictionary. Do you think this man can either love or hate? I dare say he can make the right noises – "I love you", or, "I hate you", but do they mean anything? If he is such a bad chemist and such a bad shot that he can't murder anybody, why does he think he could love people?

M: Why did he want to see an analyst?

P: He was afraid of what effect his behaviour might have on his wife and child. He wanted to be able to take care of them and was afraid of becoming incapable of working. He was also afraid of killing himself and thereby leaving his wife and child alone.

B: So what do you think he meant when he said he loved you?

P: I don't know, but I felt touched by it.

B: The question of how you feel has to be settled by you in your own analysis. The problem in the analytic session is: what does the patient mean? It may be true that you are touched, but by what? I might have been touched had I been there, but I wasn't, and I am not. But you aren't reading a story, and I can perfectly well understand that you were touched. To you it is a *practical* experience; to us it is a theoretical discussion. . . .

26

Presenter: The patient sat on the couch and said in a strong voice, "I've asked myself why I'm here today. There's a soccer game this afternoon – Brazil are playing. I enjoy soccer so much I'm sorry to miss it. I was sure that I was going to get awfully bored here. I've been thinking how bored I would be ever since I put the key in the car to come here. And I'm still asking myself why I came." I said, "I feel it is very difficult for you to admit that you do something because you enjoy it. You arrived here feeling certain that you would be bored. It seems to me that behaving like this makes you feel happy. Perhaps you are being masochistic."

Bion: The patient says he 'asked himself', but he doesn't say what he himself answered. Perhaps 'he' and 'himself' are playing another game which is also very pleasurable – a game in which he is cruel to himself and is also cruelly treated. But neither of the two people in the room can go to the football match, so both of them are cruelly treated.

P: He said, "I don't understand when you talk about things like masochism. I'm getting bored again. I've been bored ever since I woke up this morning, and I'm so bored now I feel like crying." His tone of voice was one of a mixture of anger and sadness. He went on, "There's a story about a woman that I can't get out of my mind. Fortunately she is so unbearable that I can't fall in love with her."

B: What do you think the patient understands when he is with you? Brazilian? Portuguese? Football?

P: Although he says he doesn't understand me, I have the impression that he does. I agree with your reference to a cruel game – I think that is what he was feeling.

B: Verbal language is very difficult to use for this purpose. I need some way in which I could say, 'understanding + absolute'. I mean by that, understanding, both positive and negative. What is the patient *absolutely* understanding? He is understanding psychoanalysis, but he is not understanding football – he hasn't gone to it. Having chosen to come to analysis – and also chosen not to go to football – he is able to observe two people in the room; he has a chance of seeing the game that is being played by the analyst and himself. Similarly, when you choose to give an interpretation, you are choosing what interpretation *not* to give. I could say that here in this room I am choosing not to hear the traffic. It is partly done by shutting the windows, but it is also done by shutting my mind to those noises. I am also choosing to close my eyes to things I can see in order to look at something else. There is always this problem: what to listen to, and what to be deaf and blind to.

I suggest that this patient is watching you and himself playing the game of psychoanalysis. All games are a mixture, partly fun and partly serious. But this patient is talking as if having an analysis is supposed to be something you don't enjoy. How does he then choose to come at all? Why has he not gone to the football match? Is he afraid that that international match wouldn't be fun?

You have to talk to this particular patient in a way which he can understand. Therefore it is necessary to be careful to choose words that are as simple and unmistakable as possible. I think you have to be careful about words like 'paranoid', 'schizoid', 'masochistic', 'sadistic', even though they may be commonly used and your patient may be an educated man.

M: Do you think the patient is trying to control the analyst?

B: Patients often do. There is nothing surprising or particularly wrong about it, but they would be frightened if they succeeded. I think this patient must be making progress: he puts up with the frustration of not watching a game – probably quite an exciting one, a nice way to spend an afternoon – and chooses to spend it doing analysis.

27

Presenter: The patient, a woman of twenty-four, was sent to me for analysis two years ago by a psychiatrist after a depressive breakdown for which she had received drugs. She had almost finished a course in psychology and was preparing to be married. She said that when she was twelve years old she underwent psychotherapy but no progress was possible because she sat and wept all the time. In the session I am reporting she was silent for forty minutes, wept all the time, and was apparently only aware of what I said for the last ten minutes.

Bion: She fears that the conversation, the verbal intercourse, between you and herself is going to be interrupted by a twelve-year-old who can drown it in tears. She is also afraid that intercourse between her and her potential husband will be interrupted by a twelve-year-old – or perhaps even by a one-year-old, or two-year-old.

What would I say to her? If I say, "You are feeling depressed", she can compare that with what she *knows* she is feeling. The advantage of that kind of interpretation is that I am talking about what is happening *now,* not about something that happened twelve years ago. One could say, "You are afraid that if you are depressed I will have nothing more to do with you. You are afraid that I will not go on with the analytical marriage." She, who knows most about the whole matter, can then feel whether I am right or wrong, and can help to keep me on the right track; she has a chance of knowing that I am talking about her self; and I have a chance of being able to judge what her reaction is to what I have said. The analyst and analysand can know what is going on in the consulting room, but neither of them can really know what happened twelve years ago, or what happened in the psychiatric hospital; that depends on memory which is very deceptive. It is therefore useful to dismiss both one's memories and one's desires so

that the present is unobscured. It is a great advantage for the analyst to feel that he does not have to talk about anything for which he has no evidence at the time.

P: Although she remains unchanged during the sessions, her extra-analytic life has developed; she finished her course, got married, and is doing well in a job.

B: In this psychoanalytic intercourse there is no way for the patient to know what kind of thing is born as a result. The anxiety is that it will be somebody who cries for forty minutes without stopping, and the analyst or husband will say, "I can't stand this any more – I'm off. You can keep the baby – I'm going." If you were writing a novel, the story could be: A and B meet; they love each other; they marry; they give birth to a child, C; C cries so much that the marriage breaks up.

28

Presenter: The patient has been in analysis with me for almost five years. This session took place four months ago. He started by asking if I had read a certain psychoanalytic book. He said, "It's a very good book and I noted several interesting things. It's very good indeed, but I haven't read it all because there are parts I'm not interested in. There is a part which described a duel – this is very interesting indeed because last Saturday I almost didn't go out – I was so tired I had to rest. Do you understand? I had to rest." I said, "You started on one idea, interrupted it, and then went on telling me about something else." He said, "Well, all right. Because I only read the part that interested me – because I noticed that – and because I rested on Saturday, I felt it was important." I said, "I think we are having a duel here too." He said, "Yes, but it's very difficult because what is happening is as if there were several situations which are superimposed." I replied, "You feel that if you don't try to tell me what is happening inside you, you will become confused." After a short silence he said, "When you speak I feel as if you had left a mark, like Z does." (Z is a character who wears a black mask, rides a horse and leaves his mark, Z.) I said, "He is a man who fights injustice." The patient laughed. "He cuts the braces of the sergeant's trousers and leaves the enemy with no clothes. That is why you make me feel irritated." I reminded him, "But the person he attacks is also a friend of his." The patient laughed again and said, "Oh yes, I quite agree – the sergeant is a fool." I said, "For you a friend is a fool – perhaps that is why you don't show friendly feelings towards me here." Then he fell silent.

Bion: If the patient says, in effect, that he is going to pick and choose what to listen to, one could say, "Well, I hope you will be able to choose the right things. I can see that I may be telling you some

things that you don't want to learn or to hear or to see. I can't do anything about that – go ahead by all means." I have sometimes said to patients, "If what you say is right, then I am the wrong person to come to. You hate being with me here; you hate what I say to you; you don't want to hear it. That is no problem because, as you know, there are plenty of other analysts. The door isn't locked, so you can walk out if you like." We are trying to show patients something we think would be good for them to know. So whatever they say, we should not lose sight of that fact; we are there to help. We don't agree with patients that we are there to cause trouble or to make things difficult for them. They are free to think what they like, but we are also free to be what we want to be. This patient seems to want to force you to be the sort of person that would suit *him.* You may want to be helpful, but there is a great difference between being helpful because you want to be, and being helpful because you are forced to be.

M: I am not sure that the job of the analyst is to help the patient.

B: The language is so ambiguous; so many different things are understood by 'help'. The oracle at Delphi was supposed to have carved into the stone, "Know thyself". So the idea that it is useful and helpful to 'know thyself' is not new. In that sense we are trying to say, "I will help you to know yourself. If you tell me something, I will tell it back again to you in a way in which you may be able to see yourself. I am trying to be a mirror which doesn't tell you who I am – that is of no importance whatsoever – but who *you* are. The only thing I can do to help you is to reflect back to you who you are, so that you can see in what I say to you an image of yourself. If you don't want to know what you look like, I don't mind – you need not look to me to reflect you; you can find a different mirror." We would like, if we could, not to be too turbulent a mirror, because if we can remain steady, then the patient can get a clearer image of who he is. If we change too much, then it becomes a distorting image.

An actor has learnt how to put on make-up and the clothes of different characters. If he comes to you for analysis, he can see the image in you of any particular character he chooses to assume. But when you start analysing such a person, you take off those clothes and he feels naked. This patient has shown that you make him feel naked. He is in effect saying, "I don't want you to take off my mental clothes." In fact he is asking you to make a deal with him: he will show you only what he wants to show you if you will promise only

to see what he wants you to see. In a way it is one of the weaknesses of psychoanalysis that analysands can only get the kind of analysis they deserve. We can't force them to learn.

This patient seems to be making a condition: he will come to you for analysis *if* he can get only the analysis he wants. It is as well to bear in mind that the only 'cure' he will get is *that* kind.

BION IN NEW YORK AND SÃO PAULO

1977/1978

Bion in New York and São Paulo was first published in 1980 by the Roland Harris Educational Trust & Clunie Press, Strath Tay.

Bion in New York and São Paulo

PREFACE

Wilfred Bion died in Oxford on 8 November 1979 less than a week after he was diagnosed as suffering from myeloid leukaemia. The content of this book was approved by him in 1978.

The two series of discussions form an illuminating contrast: The 1978 South American visit was Bion's third to São Paulo and fourth to Brazil; his method of presenting his subject was, therefore, familiar to those taking part. The visit to New York in 1977 was his first.

It must be admitted that for those looking for cut-and-dried 'answers' Bion's method was inexplicable, frustrating and aggravating. Here was a man, thoroughly conversant with his subject, exceptionally articulate and therefore well able to supply questioners with what they wanted to hear – and he knew it. But he was steadfast in his respect for the truth and would not be persuaded against his better judgement to follow a course in which he could not respect himself. He believed that "*La réponse est le malheur de la question*"; both in his professional and private life problems stimulated in him thought and discussion – never answers. His replies – more correctly, counter-contributions – were, in spite of their apparent irrelevance, an extension of the questions. His point of view is best illustrated in his own words: "I don't know the answers to these questions – I wouldn't tell you if I did. I think it is important to find out for yourselves"

"I try to give you a chance to fill the gap left by me"; "I don't think that my explanation matters. What I would draw attention to is the *nature* of the problem".

"When I feel a pressure – I'd better get prepared in case you ask

me some questions – I say, 'To hell with it, I'm not going to look up this stuff in Freud or anywhere else, or even in my past statement – I'll put up with it'. But of course I am asking you to put up with it too".

Francesca Bion

AUTHOR'S NOTE

I thank all who participated in these discussions with their objections and agreements. Many who read this book will feel that my replies are inadequate and incomplete. That they are inadequate I must admit; that they are incomplete I regard as a virtue especially if it stimulates the reader to complete the answers. I wish the reader as much enjoyment as I had in speaking; if it sends him to sleep may I wish him "Sweet Dreams and a profitable awakening".

W.R.B.

NEW YORK
1977

INTRODUCTION

These talks, given in April 1977 under the auspices of the Institute for Psychoanalytic Training and Research (I.P.T.A.R.), took place on five consecutive evenings. There were two groups of participants; one attended talks One, Three and Five; the other, Two and Four. Although some roughnesses and repetitions, inevitable in impromptu expression, have been deleted it is hoped that the printed record is not misleading. A few passages have been added subsequently; these are marked { }.

Q = question

O = observation

1

Bion: Well, here we are.

But where is 'here'? I remember a time when I was at an address – some seventy years ago – which I called "Newbury House, Hadham Road, Bishops Stortford, Hertfordshire, England, Europe. Another small boy said to me, "You have left out 'The World'". So I put that in too. Since then I have been told by the astronomers that we are part and parcel of a nebular universe, a spiral nebula to which our solar system belongs. Astronomers can get away with a remark like this; nobody complains that they are always 'inventing' new discoveries. But, as Freud pointed out, this is not the case with doctors or psychoanalysts. People say, "These doctors are always inventing new diseases; then they treat them. It becomes a vested interest". But nobody says "You astronomers invent a new universe and want another telescope". I suppose it is because we feel it doesn't matter very much what the Universe is.

I want now to narrow down the view, cutting out the various elements we regard as irrelevant. As analysts we look at what we call the character or personality. This peculiar view – I won't say Freud started it, but he gave it a considerable push – turns out to be a vast universe of its own kind. We forget that the dimension which Freud introduced into this scrutiny has caused a lot of trouble. We fail to notice it because we are in the storm centre, unaware of the 'centre' of which we are a part. But it is that disturbance with which we are concerned.

What does it look like to us? When we go to our offices tomorrow what do we expect to see? What are we going to look at? What is our interpretation, our diagnosis? What is our interpretation of the facts which our senses make available?

We assume that there is a mind, a personality. What does it look like? What does it smell like? Does it present itself to our touch, our feelings? Do we get any tactile impression? We know that so far we do not; so far we cannot say, "I walk into this room blindfold and I can feel a psychosis hitting up against my mind". What then is making contact? Is there any way of verbalizing this? Is there any way of communicating this thing to each other? Hypothetically, yes. Hypothetically we can write papers, we can write books about it. But what *do* we contact tomorrow? Can we say from what we contact, "I have been here before; I have had this sensation before now"? If so, what sensation?

Expanding our view again, taking the entire universe – I have been here before. Where? According to the astronomers this spiral nebula, of which our solar system is a part, is itself rotating; it is a long way from one side to the other and a long time, from our point of view, before we are at the same spot again – something like twice ten to the power of eight million light years – so far indeed that if we look towards the galactic centre there is nothing to see excepting the remnants of the Crab Nebula which is still in process of exploding. To us it looks immense because we are such ephemeral creatures.

Not forgetting that, but using it as a background, narrow down the view again and look at it through this microscopic, psychoanalytic view. We need to have some idea what we 'see', what we make contact with. It would be useful if we could feel there was something familiar about it and say, "I have seen this before", or "I have had this experience before".

To return to my own private life: When I was small I used to be regarded by grown-ups as a very odd child who was always asking questions. I was made to recite a poem:[1]

> "I keep six honest serving-men
> They taught me all I knew;
> Their names are What and Why and When
> And How and Where and Who.
> I send them over land and sea,
> I send them east and west;
> But after they have worked for me,
> I give them all a rest."

---

[1]Rudyard Kipling, 'The Elephant's Child', *Just So Verses*.

It was considered to be extraordinarily amusing that I had to recite this piece of verse. I could not see the joke myself. I was told I was just like the Elephant's Child who asked these questions – and like a fool I asked another one. I said, "Who was the Elephant's Child's father?" That was not popular; it was not amusing. But I was not making a joke. I decided I had better be careful not to ask too many questions; it took me a long time to dare to start asking questions again. The person who made it easier for me was John Rickman who was the first psychoanalyst I ever met. I am still at it – I don't think it is any more popular now than it ever was.

To return to this simple poem of Kipling's – "I give them all a rest". When we are in the office with a patient we have to dare to rest. It is difficult to see what is at all frightening about that, but it is. It is difficult to remain quiet and let the patient have a chance to say whatever he or she has to say. It is frightening for the patient – and the patient hates it.

We are under constant pressure to say something, to admit that we are doctors or psychoanalysts or social workers; to supply some box into which we can be put complete with a label. So the patient tries to diagnose the analyst, and the analyst hopes that somehow he will have a chance to "see a pattern emerge". I use that phrase deliberately; Freud was most impressed by Charcot's use of it.[1]

We have to focus our attention on the individual. It is no good talking about the astronomical universe; it is no good talking about the cosmos. But to suggest that we are people with a prejudice in favour of having respect for the individual is a dangerous thing to do because it will not be tolerated easily by the group, the crowd, the nation or the race. It is as well to be clear about this: We are involved in a philosophical prejudice in favour of a person, in favour of the uniqueness of the human individual. There will be an emotional pressure against each single one of us who dares to attach importance to an individual and who dares to be an individual himself. We may long to say, "I'm American", or British or Freudian or Jungian or Kleinian – any label which is 'respectable'. But every psychoanalyst has to have the temerity, and the fortitude which goes with it, to insist on the right to be himself and to have his own opinion about this strange experience which he has when he is aware that there is

[1]S. Freud, *Introductory Lectures on Psychoanalysis* (1916–17).

another person in the room. Pressure against this is considerable; your senses tell you that it is your office; you are used to the windows here, the furniture there; there is every pressure to make you feel you are at home. It is difficult to resist that. I have suggested this: Discard your memory; discard the future tense of your desire; forget them both, both what you knew and what you want, to leave space for a new idea. A thought, an idea unclaimed, may be floating around the room searching for a home. Amongst these may be one of your own which seems to turn up from your insides, or one from outside yourself, namely, from the patient.

Here is a dismal story: the patient has been coming to you for the last five, ten years. If you were honest you would have to say that you are sick to death of the sight of that patient; and if the patient is honest he would have to say he is sick to death of hearing about psychoanalysis or seeing his analyst. It is not polite to talk in that way; nor is it helpful.

We should retain civilized and conventional politeness. It exceeds the limits of the necessary minimum conditions for psychoanalysis to resort to violence such as breaking furniture, though an analyst may tolerate such behaviour temporarily. A child – of whatever age – can be expected to behave reasonably politely. {Each analyst must be clear in his own mind what for him are the minimum conditions necessary (MCN) in which he and his patient can do the work.}

Let us widen our view, taking a biological vertex. So far the human animal has been extremely destructive; it hunts in groups, in herds, and has managed to kill opposition from other dangerous animals – even tigers and lions. {Analyst and analysand are alone in the same room. The MCN are that both behave in a conventionally civilized and polite manner. They are still dangerous animals, so we can see that the limitation proposed by psychoanalysis itself restricts their behaviour. We also indicate (and provoke, albeit unintentionally) primitive behaviour.

The psychoanalytic conversation is itself an experience of conflict between the phenomena to which attention is drawn and the MCN for the work. If this fact, often unobserved, were allowed for it would make it possible to understand why the analyst and the analysand are fatigued by the strain of a psychoanalysis.} Annoyance between analyst and analysand is likely. We can use technical terms like 'transference' and 'counter-transference', provided they illuminate rather

than obscure. But the thing itself doesn't go away because we have given it a name; whatever they are called, the feelings of the couple remain. Starting from the moment of birth we are always supposed to be learning to behave in a civilized way. At an early age we have already learnt not only *not* to be ourselves but also *who* to be; we have a well-established label, diagnosis, interpretation of who we are. But the *facts* continue to exist. What the patient says can be used by the analyst as a free association. {This may be mistaken by the analysand as a way of ignoring the facts which he has communicated. It is necessary for the analyst to be clear in his mind that this is not so.} In due course a pattern will emerge which can then in its turn be interpreted. As a by-product the patient can discover who he is. So few people think that it is important to be introduced to themselves, but the one partner the patient can never get rid of while that patient is alive is himself.

Q: How do you proceed in helping the patient to discover his true self?

B: It is difficult to borrow from a newly developed 'sense' – of self-awareness – to illuminate the fundamental and basic thing. I try to give myself a chance to absorb that basic thing. Our common senses tell us that there is another person in the room; the basic 'thing' – not the 'common sense' – is what I wish to make explicit. I cannot describe what a 'person' is, but I am sure there is such a thing, and I am sure it is not adequate to describe what presents itself to my eyes, my ears or even what could be recorded by a video-tape. It is too crude; there is something else in the room.

If you show a musician a sheet of music he can see the black marks on a white background but he behaves as if there is something beyond that. The painter sees a field of poppies – which everybody has seen – and paints a picture of them. You may see a reproduction of it – it doesn't mean a thing. If you walk into the Jeux de Paumes in Paris and see the painting itself, you think: "I never saw a field of poppies until now; *now* I know what it looks like" – it is an emotional experience, not a report on one. How does a great painter manage to use pigments and canvas to give countless people an idea of what a field of poppies looks like?

Shakespeare writes a simple piece of prose: "The raven himself is hoarse that croaks the fatal entrance of Duncan under my battlements". All the words are simple; "battlements" is the longest one

and doesn't take a moment to look up in the dictionary. But, "The raven is hoarse that croaks the fatal entrance of Duncan under my battlements" – that is something else. What else is it?

I am well aware that you are not going to see a Shakespeare or a Monet in your office; the person will be disguised as Mr or Mrs X of such-and-such address. Don't be taken in by that; don't be taken in by the fact that you think you have seen this patient before – you have not. What you have seen before doesn't matter. What does matter is what we, the analyst and the patient, have *not* seen before. Prince Andrei, in *War and Peace*, says on hearing a remark, "That is sooth, accept it – that is sooth, accept it". We likewise can feel, "Yes, that is true. That interpretation is right; that observation is correct". That is contact with the *thing itself*. Unfortunately it doesn't happen as often as we would like; the two personalities do not often meet. But they may meet closely enough to be aware that there is something more in the room than a computer can process.

The infant knows what it is to have raging emotions – things to which we give crude names, like fear, depression, love, hate – but it doesn't know what to call them; by the time it has mastered articulate speech it has forgotten what it feels like to be an infant. So we, who have reached this stage of being capable of articulate speech, have almost forgotten what it feels like to be human. We spend too many impressionable years in learning how to be just like everybody else – not how to be ourselves. Now we spend too many years in the intellectual stratosphere. But despite what we have learned, certain 'crude' feelings are still able to make themselves felt; if they can dare, the analytic couple can still feel love and hate.

The analyst is trying to help the patient to dare to be himself, to dare to have enough respect for his personality to be that person. The analytic experience, in spite of all the appearance of comfort – comfortable couch, comfortable chairs, warmth, good lighting – is in fact a stormy, emotional experience for the two people. If you are an officer in a battle you are supposed to be sane enough to be scared; but you are supposed also to be capable of thinking. It sounds ridiculous to say that people sitting in a comfortable room in full peace time have to be capable of anything – but they do. The analyst is supposed to remain articulate and capable of translating what he is aware of into a comprehensible communication. That means that he has to have a vocabulary which the patient may be able to understand if given a

chance to hear what the analyst has to say. It sounds absurdly simple – so simple that it is hard to believe how difficult it is.

The language we use is so debased that it is like a coin which has been so rubbed that it is impossible to distinguish its value. "I'm terribly frightened" says the patient. What about it? Terribly. Frightened. These words are commonplace. But I now become alert when I hear that word "terribly" because it is so worn. It's terrible weather; it's terrible this; it's terrible that; the word means nothing. {When the patient becomes aware of the analyst's attention he will find a more arcane way to say "terribly frightened" – perhaps even a 'psychoanalytic way'. The game of hide-and-seek will enter a new phase.}

Q: When psychoanalysis works I think it gives the patient a sense of conviction of what it is about. I feel our efforts should be directed towards finding what is lost, what is *not* stated.

B: What you say seems to come near to what Melanie Klein tried to say; it illuminated things so much that it revealed still greater vistas of darkness, unilluminated areas. In psychoanalysis we are always unveiling still further domains of ignorance, darkness, the Void. Melanie Klein said that patients have omnipotent phantasies, that they split off parts of the personality and project them into the breast. She meant what she said and I think that was correct – as far as it went. What I am not so sure about it that it is *only* an omnipotent phantasy. I have experienced the situation in which the patient can arouse in me feelings which have a simple explanation. You could say, "Anybody would know why the patient makes you feel like that; you need to have more analysis". That is true, but it is not the whole truth. I think that the patient does something to the analyst and the analyst does something to the patient; it is not just an omnipotent phantasy.

When a pattern emerges which the analyst wants to communicate to the analysand he has to use a formula that the analysand is capable of receiving. An expert diamond cutter can cut the facets in such a way that light which is reflected onto the diamond is thrown back again – with increased brilliance – by the same route. That is why the fine precious stone sparkles. {This model is itself an example of my attempt to make clear to you what I wish to illuminate. The analysand, by coming, gives the analyst an opportunity to observe his behaviour – including both what he says and does not say. Out of the totality of what the analyst is aware of he detects a pattern. When it is sufficiently clear to him he can decide whether he can convey it in

a language comprehensible to the analysand, augmented in a manner analogous to the model.} Thus the analyst can hope to reflect back the same illumination given him by the analysand, but with greater intensity.

Patients sometimes wonder why we are so uncommunicative; why, for example, we don't tell them whether we are married, or whether we have any children. We don't tell them these things for good reasons; they can get so filled with knowledge about the analyst that there is no room for the exercise of their own conjectures and, therefore, for the development of their own capacity to think. {An inherent difficulty in analysis is that any interpretation tells the patient something about the analyst. It would be no easier if the analyst deliberately concealed his true personality. All that he can do is to avoid or allow for that distortion.}

I can say to the patient, "You are feeling that I am – such-and-such"; that is not information about myself as the analyst. I hope that the patient will be able to recognise it as his own idea – hitherto unrecognized. It requires courage on the part of the patient because he is terrified of learning something about himself which he has never wanted to know and which he has spent his life not being aware of – probably from before birth – trying to learn what he *ought* to be.

Where does this 'ought' come from? Have we, as analysts, told them what they 'ought' to be? If, as we hope, we have not then this 'ought' must have come from somewhere else. *Immediately* it has come from the patient; where has it come from *mediately*? One hopes to be able to give the patient a chance of finding out.

Q: Is there any way of knowing if you are not kidding yourself?

B: {This question touches the profound problem of Truth. Through the ages anyone who has felt the urge to know the truth has rapidly found himself confronted by this question – can any human being validate what he thinks is true? Psychoanalysis cannot be practised without becoming aware of that problem; at every juncture of the analytic experience it could be expanded thus:

1. What is the analysand's behaviour?
2. What aspect of it enshrines the truth?
3. Have we observed his behaviour correctly?
4. In so far as we have observed it correctly what have we observed?

5. Knowing what we know now, is any human being who aspires to the truth engaged on more than a fool's errand? I doubt that any of us can escape this; {even apodictic 'knowledge' is vulnerable.}

To return to the problem of language: {Terms such as 'counter-transference' have suffered debasement through the popularization of psychoanalysis. It is probably no worse than the popularization of physical medicine and surgery which leads to applications of a home-made poultice to a cancerous sore.} One of the essential points about countertransference is that it is *unconscious*.[1] People talk about 'making use of' their counter-transference; they cannot make any use of it because they don't know what it is. There *is* such a thing as my emotional reaction to the patient; I can hope that through my awareness of the fact that I have human characteristics like prejudice and bigotry I may be more tolerant and allow the patient to feel if my interpretation is or is not correct. That is a transient experience. It is one reason for calling it 'transference'; it is a feeling or thought or idea you have on your way to somewhere else. When you are in the presence of something which you have learnt to call a transference can you feel more precisely what it is at the time? It depends on what the patient says to you being allowed to enter into you, allowed to bounce off, as it were, your inner being and get reflected out.

Q: Are you suggesting that it is not so much your reaction to the patient in terms of your interpretation – which is undoubtedly contaminated by your counter-transference – but rather the atmosphere in which the patient is provided with the opportunity to transfer and to explore being?

B: I think the patient ultimately has the chance of learning that. He may get the idea that there is something to be said for analysis and for the time and money spent on it. The time it takes cannot be measured by the months or years the patient was coming to your office; the after effects of that experience persist.

Q: Doesn't the language of psychoanalysis take one away from psychic reality? Since it is mostly sensuous imagery, and psychic reality is essentially non-sensuous, one has to be careful how one uses psychoanalytic thoughts for language.

B: The founder of University College, London, was a man who

[1][A point emphasised strongly by Hanna Segal (1977). *Ed.*]

had studied philosophy at Oxford. His summary of that experience was that the only thing he had ever learnt was dissimulation and lying. Indeed, one of the earliest achievements of articulate speech is just that; how to make a fool of other people – which often involves making a fool of oneself as well. So your question is a fundamental one – how is verbal communication, which has such a long history of use for purposes of deception, dissimulation and lying, to be reconstituted to further the progress to truth. It is a question which you have to answer for yourself; you have to find out what the vocabulary is that comes most naturally to you and which you can continue to use, and so restore some of its value for this particular purpose of helping people rather than sinking them.

Q: Do you work with families?

B: I prefer them not to get through my office door. I cannot of course guarantee to keep them out mentally. I consider I am trying to analyse the patient; what his family are doing to him I don't know and I can do nothing about them. I feel there is a lot of unexplored and unexhausted territory which can be investigated only analytically. If you think you can cope with the further experience that an entire family could bring I do not see why you should not do so; it is not my choice. I attach a great deal of importance to the experience that I am permitted to have if the patient will come to my office and stay there for fifty minutes. The moment the patient is out of my sight and hearing, the value of the experience falls off fast. Hearsay evidence is worth very little to me. I hear all sorts of things about myself, about my patients, which are to me not much more than a meaningless noise. "It is a tale told by an idiot, full of sound and fury, signifying nothing". The chance you are given by exposure to the patient's personality is invaluable; it is difficult to know how to get fifty minutes worth out of it.

Q: Your work with groups suggests that within that matrix there are certain basic assumptions going on. Could you not conceive of a family situation as a group situation? Might there be some basic assumptions at work with all sorts of underlying archaic processes that are worth exploring too?

B: Yes, there are. Freud said it is important to analyse the Oedipal situation. What is the Oedipal situation? Who are the characters? Father, mother, child? Can you be sufficiently exposed to the change that occurs when a patient walks into your office to be able to

communicate first of all with yourself? To do this you have to forget, denude, your mind of what you know, so as to have yourself free to what is going on. Then as you watch the 'screen', can you see any pattern flicker into position? Who are the characters who are in search of an author? You will have to be the author; and when you have this play clear you could mention it to the patient – that would then be your interpretation. I have also described it as "thoughts in search of a thinker"; I have to be exposed to it on the off-chance that some stray thought might lodge itself in my mind – or if not mine, the patient's. It might then be verbalized.

If you find mathematics provides you with a more convenient language – I am still talking about your communication with yourself – then you might decide a triangle would represent it. But so many people have heard of 'the eternal triangle'; it has become a debased, meaningless phrase.

Again falling back on a model: The ancient Egyptians discovered that if you knot a piece of cord in the proportions of 2, 4 and 5 and join them up in a triangle, then you have a right angle and can build places like Thebes. Pythagoras – or so they say – discovered the Pythagorean theory. It is illuminating, a mental can-opener; it gives you a chance of opening your mind and, if you are lucky, finding inside a thought or two which might come in useful for an interpretation. Can you then verbalize it in such a way that the patient would understand your language? I am familiar with thinking I have discovered an interpretation, and have taken a long time giving it, only to be told by the patient, "I don't know what you are talking about".

People are educated to believe that they ought to behave in a civil manner, that personal remarks are impolite. It is difficult to realize that the patient often cannot stand hearing what we have to say; the analytic conversation with which we are familiar is not familiar to him. Although the words are in common use the meaning that they are to convey is not; the patient is being exposed to an experience which is usually nasty and which is also unknown.

Q: How does it differ from other situations in which one person is communicating with another, like that of a mother with her child or other didactic relationships?

B: What makes it unique is that there are two unique people in the room. The more respect one has for the individual the more obvious it is that there is no other 'you' and no other 'him' or 'her'.

On the other hand, there is something wrong with an analysis which doesn't remind both the analyst and analysand of real life. What is it about if it has no resemblance to the universe we live in – a universe of ideas and thoughts and feelings? If we can get near to verbalizing and describing what we want to convey, then the patient can recognize that we are talking about what is available here and now reminding him that similar situations exist elsewhere which are likely to occur over and over again. We are not talking about something which happens only in an office or only within the limits of what we call psychoanalysis, any more than one could say that a2 + b2 + 2ab is only an algebraic formula. It is of application; these proportions exist in different situations; situations where people want to build vast temples which stand up by themselves at right angles to the earth and to the foundations.

Q: I wondered why you said it was a "nasty" experience. You also said that the patient and the analyst can get bored; at another point you said that it was a very exciting experience. It is clear, listening to you, that you consider it a special and intimate experience.

B: I can take one of the examples you mention. I remember a patient who was so boring that I became fascinated by how he did it. How could this man converse with me in a way that was nearer to what I would call 'pure boredom' than anything I had ever experienced? That is why it is fascinating; your curiosity is stirred up.

Q: Did you figure it out?

B: I would like to be able to write a book on the hundred and one versions of boredom – if I had the skill or the time to do it. If you can stand the boredom of it you may be able, like the patient, to put up with it long enough for something to flicker into place, something which you could then translate into words. The patient keeps on talking about something which one could describe as a transference relationship, but the two things which might anchor it are missing; there is only the bit in between. It becomes a sort of 'pure' psychoanalysis; it is nothing but transference with nobody else in the room – and that is extraordinarily boring to hear. You recognize after a time that you are being told something by the patient, but never a fact within sight or hearing. You know nothing about the patient; you know nothing about the patient's private life. What interpretation are you to give? In a sense you could say it is an analogy, but a pure analogy; not the two things on either side, only the link in between. Translated

into biological terms: What is this? A breast? A penis? No baby? No mother? Only the thing in between? Is this 'pure' psychoanalysis; all sex, but not a relationship between two people? This peculiar situation is not simply a question of semantics, not a question of learning grammar.

This is an actual event which is taking place in front of you, a demonstration of what joins two people, but with neither person present – they are both missing. What then is the link? If we don't bother about the two people, what about this thing in between? If it is neither a breast nor a penis, could it possibly be a vagina? Could it be a non-object. It is possible for what we biologically call a 'woman' to have a sexual relationship with another person?

2

Bion: "Well" . . . "I mean to say" . . . "You know" . . . I can go on like that for hours. It is the wreckage, the remnants of thought. Patients often want to tell you something, but all they have with which to do it are the remnants of articulate speech. So the first thing you are confronted with is the remains of a culture or civilization. We try to be as conscious, as wide awake, as logical as we know; to have all our wits, all our experience about us to do the work of psychoanalysis. But is that state of mind one which can make contact with a different state of mind?

Freud gave meaning to words like 'conscious' and 'unconscious', drawing attention to the fact that there is a state of mind which is different from what we usually call 'conscious'. I am not sure that he made a clear cut distinction between what he was talking about adjectivally – unconscious modes of procedure, unconscious modes of thought – and *the* unconscious as if there were such a thing. These concepts, these theories match up with what most people vaguely recognize, partly because we all think we know the language, but we know a debased language – a vague language.

I don't think this idea of *the* unconscious, or even the idea of unconscious thoughts or ideas, extends far enough. It is surprising how far Freud got with those theories and the extent to which he made his own work redundant. He opened up still further areas of experience which cannot be treated in the way in which we attempt to treat neuroses and those phenomena in which this idea of the unconscious and unconscious thoughts – the substantive and adjectival words – are indicated.

I draw attention to the existence of what seem to be primordial ideas and feelings which have *never been conscious*. They are different

from ideas which have been conscious at some time and have been repressed, or have been transformed into something which is unconscious. That realm which we often think of as being somewhat irrational is in fact rational – if seen from another vertex. If you have an experience about which you can do nothing you forget it – it is obvious common sense. If you have a tooth-ache and there is nobody to look after your teeth – forget it. If you have an ache in your mind, forget it. But psychoanalysis seems to indicate that that is not good enough because when this thing has been forgotten – as I think, correctly – it goes on leading an independent existence and then gives rise to symptoms and signs of its activity although we are not conscious of it, although we have 'forgotten' it. Does the same thing apply to something which has never at any time been conscious?

As I said before[1] patients sometimes behave as if they were in fact – not phantasy – splitting off parts of their personality and pushing them into my insides. Sometimes I wonder why I begin to feel angry or alarmed in a session; I am not able to dismiss the feeling that the patient is doing something to me, actually having an effect upon me. We can deal with this sort of patient by saying "Psychotic – incurable. It's time the analysis was terminated because this is beyond analytic capacity". We hope some psychiatric hospital will kindly take charge of the patient and lock him up safely. In that way these awkward patients cease to disturb our peace; we have them safely under lock and key; we have them mentally categorized in a mental box; they are psychotics, they are finished and done with – but the sufferer remains. To succumb to that impulse gradually erodes the psychoanalyst's integrity.

Suppose an intelligent, powerfully mentally equipped man and woman have biological sexual intercourse and bring together ova and spermatozoa which initiate cell division. According to the embryologists, cell divisions take place and at the 3 Somite stage optic and auditory pits are formed. In this period the cell division is going on in a watery fluid which is polluted. (I am taking as pure fluid extra-cellular fluid which seems to have the composition which sea water had before it became sea water. The extra-cellular fluid is the nearest thing you could possibly imagine to an absolute stage when

[1][See in Talk 1, where Bion mentions Melanie Klein and omnipotent phantasies. *Ed.*]

the world was surrounded with water before the water was polluted with earth products.) Changes in pressure in this watery medium are easily communicated. The amniotic fluid can be subjected to changes of pressure through uterine contractions for example; there may also be pressures extraneous to the mother – she can be shouted at, pushed about. If you put pressure on your eyeball – and if someone is so unkind as to do it suddenly and violently – you can be said to 'see stars'; you get an impression of light. But that is an anomalous response. {One day the remnants of that anomalous response can emerge with a force that disconcerts both patient and analyst. The analyst is told that the patient suffers from intense, bright colours or fortification patterns or, possibly, migrainous headaches.}

When do the auditory or optic pits become functional? When is there some kind of primordial sight or hearing? By the time there is an autonomic or sympathetic nervous system – a 'thalamic' brain – the embryo may be experiencing something which one day might be called 'hate' or 'fear'; {contemporaneously an impulse to fight or run away. The thalamus and limbic nuclei will one day be the origins of fear and aggression, dancing and combat. For convenience we can describe this briefly as 'sub-thalamic' behaviour.}

Suppose the foetus arrives at what the obstetricians call 'full term'. Does the foetus have to be born before it has a personality or a mind? Conversely, does man have a mind? I see no reason to doubt that the full-term foetus has a personality. It seems to me to be gratuitously nonsensical to suppose that the physical fact of birth is something which creates a personality which was not in existence before then. It is much more reasonable to suppose that this foetus, or even embryo, has a mind which one day could be described as highly intelligent. {We shall have to consider this point further if we have an emotional impulse to relegate one of our patients to a category of 'hopeless' or 'psychotic'. Before acting on such an impulse we need to ask ourselves whether 'hopeless' or 'psychotic' is a description which illuminates *our* state of mind rather than that of the patient.}

Q: What about the question of myelination of nerve endings, the idea that there can be some sort of neurological recording in an integrated centre in terms of registering information within the young person's mind?

B: {Is it possible that the hypochondriacal areas attempt to communicate with the cerebrum; that the autonomic nervous system

tries to communicate with the voluntary system; that the body tries to communicate with the mind – assuming that there is a mind?.} Physicians and surgeons interpret these pains: It is difficult to do. For example, a patient once said to me, "I've got water on the knee doctor". I palpated it and sure enough there seemed to be a bursitis. The patient was a charwoman who used to do a good deal of kneeling and it mattered to her that her knee was giving her trouble. She also complained about some difficulty in holding her water. She said, "When I cough I always pees a little". She gave a little cough and said, "There, I peed again then". I said, "As a matter of fact you have coughed quite a lot here haven't you?"

"Oh, that's nothing. I've always had this cough". At this point I had a vague idea that I had come across the lymphatic system in Grey's *Anatomy*; I said, "We'd like to have an X-ray of your chest". There it was. Foggy patches; obscurity. The path. lab. report on the knee fluid was 'tubercular'; the tubercle had tracked down from the lungs and turned up in the knee.

{That diagnosis was based on sophisticated medical theory. My 'vague idea' was a rational conjecture. Could there have been some direct mental link in the patient's mind between a sore knee and a cough reflex?} Is there mental 'stuff' distinct from the physical network of communication? The theories of Freud, Klein, Abraham and others presuppose that there is. I subscribe to that belief and the experience of psychoanalysis is to me convincing. It is, however, equally clear to me that this is a 'probability' and not a 'certainty'. An austere judgement would not concede 'certainty' to the lymphatic system; that is typical of the still unexplored means of communication, the myelinated fibres you have just mentioned, the neurological mechanism, the parasympathetic system, the system by which the body makes what it has to say noticeable up at the cranial end for which superiority is claimed, even a social superiority, to what goes on at our tail ends.

I suggest that there is something which can communicate itself from the full-term foetus, and possibly earlier than that, to the mind as we know it. Why should the symptom, the sign of some trouble or defect, not track its way through channels – about which we as yet know nothing – to appear in the area of articulate speech? In other words, the articulate speech betrays a symptom which then we attempt to analyse. Would it be possible to say that certain mental

articulate symptoms, if correctly interpreted, could lead a surgeon or physician directly to a physically disturbed organ.

In the optic chiasma so many channels are close to each other – the basal nuclei and the basal ganglia can be interrupted as they would be by surgical interference in a lobotomy. Similarly a tumour there betrays itself in a variety of manners. It might be possible to say, "The way this patient talks to me shows symptoms of a physical disorder which are as clear to me as are the meanings of a sign like pallor, signs of anaemia". Following psychoanalytic principles, it is clear to me that the analyst should be alert to the tracking of symptoms in both directions. {The problem is not a mind with one track, but a track which is one-way.} If certain symptoms can make themselves emerge on what we call 'conscious, rational levels of thought', then conscious, rational levels of thought should be able to be made operative at the point of origin of the 'dis-ease'. Is it possible to make an interpretation which also tracks its way back by the same path to the origin of the trouble? If so, then psychoanalysis may be able to have some effect on things which at present appear to be inaccessible to treatment.

Q: If infants or patients do not simply have a phantasy that they are splitting off parts of their personality and evacuating them into mother or analyst but are actually doing it, what do you see happening? What is it that they do?

B: I take refuge in the idea of the Grid in this way:– Things which are called material can be regarded as being outside our province because they are facts of physical make-up. But – and here I am entering into grounds which I am sure would be controversial, and rightly so – I would also now suppose that, besides these theoretically supposed imaginary beta- and alpha-elements, thought enters into a phase which I could call *primordial*. I could say that the primordial thought also betrays itself here – I am talking about *us* – but now I would call it a speculative imagination. This kind of thought has nothing to do with 'evidence' – it is speculation. I encourage people to indulge their speculative imagination; there is a lot to be said for it before it turns into something a scientist might call 'evidence'. The sort of things which float about in this area of speculative imagination are rationalizations, phantasies, probabilities – not facts.

This analytic activity upon which we are engaged does not seem at present to be supported by apodictic evidence, but I think we are justified in saying that probably psychoanalysis is some use, probably

the outcome of certain conversations which I have had together with somebody who is not me has been responsible for initiating further development. A diagnosis like 'psychotic' or 'borderline psychotic' does not allow room for elaboration, speculation, conjecture; it limits the possibilities of expansion. Analysis should not be so restricted that there is no room for development and growth. I can imagine – an imaginative conjecture – that the walls of the uterus might be so restricting that there is no alternative but for the mother to evacuate the creature which is inside, and for the creature which is inside to get out and make an adjustment from life in a watery fluid to life in a gaseous fluid. Then the parents likewise must develop – from husband and wife to father and mother – otherwise there will not be 'space' in which the neonate can develop.

Q: Coming back to the question of how you know about the possible projection from the patient into the analyst, whether it really happens, what about the way the analyst feels? The analyst, who usually feels comfortable, pleasant, suddenly in the middle of a session feels irrationally angry. Is that something the patient is doing to the analyst? Is that a counter-transference? Is that evoked?

B: What we *feel* is as near to fact as we are ever likely to get in this extraordinary occupation. While we are prepared to argue about the various ideas that we have, we are not prepared to argue about, "what it feels like to be me". I can compare what it feels like to be me with what somebody else *says* that I am feeling like. The patient knows much more about what it feels like to be him or her than any analyst. So it is important to work on the basis that the best colleague you are ever likely to have – besides yourself – is not an analyst or supervisor or parent, but the patient; that is the one person on whom you can rely with confidence to be in possession of the vital knowledge. Why he doesn't simply make use of it I don't know. The human being is an animal which is dependent on a mate. In analysis it is a temporary mate; when it comes to life itself one would prefer to find somebody not oneself with whom to go through the rest of one's living days. The biological unit is a couple.

O: You talk about the mother 'evacuating' the foetus, the patient 'evacuating' either into the mother or the analyst. Then you say that the patient can tell us whether or not our interpretation is correct. It would seem as if the feeling or material the patient has evacuated still remains very much with the patient so that he can either tell us

we are correct or incorrect, or whether it is rubbish. I am trying to understand what you mean by 'evacuation' in that sense.

B: I don't think you will ever understand that except in your office. There at least it is possible to have an opinion as to what it is. You can narrow down your view as if you changed your telescope for a microscope directing it in the area where you would be likely to find an answer to that question. I can easily indulge in speculative imagination and say I think the patient does evacuate something, but it is worse than useless if what I say is used as a substitute for the analyst's own observation.

Q: Reading your work, it is obvious that you choose your language extremely carefully. Re-phrasing the concept of evacuation and some other terms, what is lost from your idea if I say, "The patient who is not in touch with certain feelings, hasn't even got them articulated but experiences them at some level, is nevertheless very skilled in subtle ways at stimulating these feelings in another person"? Does that lose some of the meaning?

B: Looking at it in a highly intellectual way, one can make some use of Kant's idea: Intuition without concept is blind; concept without intuition is empty. Translating that into familiar language I could say that some patients are describing a fact intuitively when they say, "I am terrified", or "I am bothered by a stammer", and you hear no stammer at all – but the patient does. That intuition remains blind because he has not been able to match it with a concept. {Your version, your interpretation is the right one if it makes what you observe clear to your patient; to use *my* version would be incorrect.}

Q: You said we can make certain assumptions about the vestiges of the early impressions, both pre-natal and post-natal, but you spoke about a patient who was provoking anger in you. Could you give us a clinical example of how you would handle that – whether you relate it to the vestiges, whether you relate it to what you are feeling?

B: I doubt it, because what I would think of would be what I would like to believe I did.

Q: We could start with that – what would you like to believe you did? What would you tell the patient?

B: I would *try* to tell the patient what he had told me. The patient says, "I had a terrible dream last night in which I was having intercourse with my wife". I could say, "If that is what you were doing what are you telling me this for? What you did or what you dreamed

is a matter of no importance. You must be trying to tell me something which *is* of importance because I don't think you are coming here to waste your time and money sitting in my office. I suggest that this story of yours has a meaning which is not yet known to either of us". *That* unknown is what requires illumination.

The ordinary meaning doesn't cease to exist, but it is not important. This apparent statement of fact is actually a formulation of a question; it is a question disguised as a fact; it is covered up; it *sounds* like a fact. And when the patient says he "dreamed" it he is also claiming that it is a fact of the kind with which we are all familiar; it is socially acceptable; we are permitted to dream things like this; it is excused.

Q: In this hypothetical situation in which you tell the patient you don't know and he doesn't know, what would happen?

B: The answer to that is again, "I don't know".

Q: What would you tell him?

B: What I said I did; it was an expression of precisely what I mean. It may be a defective and inadequate and insufficient way of saying it, but I know of no other; and I think it is fair to assume that the patient knows no other way of saying it. If these thoughts are not in fact limited to the times when the person is asleep, if the patient has that same so-called 'dream' in broad daylight when he is wide awake, then somebody is liable to call it an hallucination or a delusion or a psychotic state. So there is a great deal to be said for saying "I dreamed it – it was only when I was off my guard".

After a time it becomes unmistakable that the way in which you talk to your patients seems to have an effect on them. Nobody can tell you that – you have to find it out for yourself. You have to be a practising analyst before you discover that it is worth your while talking to patients in the way that *you* talk to them – never mind whether it is sanctified by appearing in one of the Collected Works. That experience convinces you that it is worthwhile having some respect for your Self – for what you think and imagine and speculate. There is a curious kind of conviction about these occasions where what you say has an effect which is recognizably similar to your theories. A 'marriage' is taking place between you and you; a marriage between your thoughts and your feelings. The intuition which is blind and the concept when is empty can get together in a way which makes a complete mature thought.

Q: Earlier[1] you suggested that current theories of borderline states don't allow room to increase the patient's space. Could you explain that?

B: The status of what I am saying is speculative imagination; I have no supporting facts, but it seems to me to be worth labelling as 'probable': If the germ plasm is potentially perceptive, having derived from both these supposedly perceptive parents, then I can imagine that even in the womb that creature becomes aware of certain 'things' which are 'not self'. For example, I could suggest to you here, "Don't let's say a thing; let's shut the windows, make this place as silent as we can". What do we hear? If that could be carried out as an experiment then we could hear our heartbeat, the surge of blood in the arteries. It is possible that the foetus is aware of a primordial 'sight', of light, and can much dislike these impingements of experiences which seem to come from outer space – sensations of light, sensations of noise – and also from somewhere which may appear to be internal – the heartbeat, the blood rushing through the arteries. That might all be so intolerable that the foetus would – to use our conscious terminology – forget it, get rid of it, have nothing whatever to do with it. Then the infant is born; but this inheritance of great potential intelligence still survives. So the highly intelligent infant can learn the trick of behaving exactly and precisely in the way in which it is supposed to behave. To take a disastrous example: Leopold and Loeb decided to commit the perfect crime. In English law there used to be a touchstone called the M'Naghten Rules: Can the patient distinguish between right and wrong? Of course he can. You cannot expect highly intelligent people not to have learnt the trick of being able to know the difference between right and wrong. So there they are – on the first step towards conviction because they appear to be responsible people. I suspect that the experience of birth is too severe; what they did potentially, when they were embryos or foetuses, is no longer available to them. They do not have this fundamental feeling, knowledge of the difference between right and wrong. There has to be some ability to make a distinction between right and wrong, between real truth or compassion, and real evil – and that

[1]See mention of Grid earlier in this Talk.

is different from knowing what people *call* the difference between right and wrong.

Q: You have written about the assumption of a psychotic core in each individual. Is this somehow related to pre-birth experience, to intra-uterine experience?

B: I think the intra-uterine experience is one which we have got used to forgetting. We like to feel that we are born and become intelligent and rational human beings, that the 'state of mind' when we are awake and conscious is superior to the 'state of mind' when we are asleep. We have a prejudice against the other state of mind – that is to say, the one in which we are not. So we try to keep the caesura in good repair; to change it into more psychoanalytic terms, to keep our resistance in good working order to act as an impermeable membrane through which thoughts and feelings and ideas of which we have disapproved at one time cannot penetrate. At the same time the thoughts and feelings that we did know at some time still strive to break loose. I could put it like this: We are all bad analysts, but every bad analyst has a good analyst inside him struggling to break free – and we hate it. We say, "My God, I'm having a breakdown! Thanks to this frightful analyst of mine my defences have been weakened and now I'm going to turn into some sort of monster and shall get locked up or commit a murder. If I'm going to commit a murder I'll start on my analyst before someone starts on me." This seems to be a situation in which there is an attempt to break through into freedom; *and* an attempt to prevent anything of the kind from happening. None of us can be free from hatred of analysis and the analytic experience, whether it is engendered by our own knowledge and experience, or whether by the sort of thing which is said to us by a patient who wears his id outside, and his ego and superego tucked away inside – and who also behaves in a way which makes it clear that his is the proper state of mind.

O: I feel like a blind man led by a seeing dog. But is it that bad? No; I am not that blind and the dog cannot see that well. What I can see is that the foetus can feel something and can have certain sensations, perhaps even certain thoughts, because the nuclei of sensations, thinking and so on, are already there in a biological way. If you take a cell and touch it, then the cell contracts and defends itself by a secret war against the impression from outside. If a protoplasm can already defend itself that much, then certainly it is possible for the foetus

to feel and to have a certain defence. I am reminded of the work of Ferenczi who compared the foetus in the water with the biological development of life on earth. That is exactly what I think Dr Bion meant, but that was described already by Ferenczi.

B: My surgical chief, when I was a medical student, was Wilfred Trotter – who wrote, "The Instincts of the Herd in Peace and War". He drew attention to something which seems to exist. For example, take a group like this: We have a combined wisdom which is extraneous to the little that each one of us knows, but by analogy we are like individual cell bodies in the domain which is bordered by our skins. I think there is something by which this combined wisdom makes itself felt to a great number of people at the same time. We like to think that our ideas are our personal property, but unless we can make our contribution available to the rest of the group there is no chance of mobilizing the collective wisdom of the group which could lead to further progress and development.

There are certain highly intelligent people who cannot stand the perpetual bombardment of thoughts and feelings and ideas which come from all over the place, including from inside themselves. So they cancel their order for the newspapers; they withdraw their number from the telephone book; they draw the blinds and try as far as possible to achieve the kind of situation in which they are free from further impact. So the community loses the contribution that individual can make and the individual mentally dies – in the same way that certain cells in the body necrose. The body has the intelligence to resist an invasion of foreign bodies like bacteria – or even plants, cocchi – and mobilizes phagocytes to deal with these invading objects. Is it possible that we can organize ourselves into communities, institutions in order to defend ourselves against the invasion of ideas which come from outer space, and also from inner space? The individual is frightened of even permitting the existence of speculative imaginations of his own; he is afraid of what would happen if anybody else noticed those imaginative speculations and tried to get rid of him on the grounds of his being a disturbing influence. Freud[1] quotes a

[1]["I treated my discoveries as ordinary contributions to science and hoped they would be received in the same spirit. But the silence which my communications met with, the void which formed itself about me, the hints that were conveyed to me, gradually made me realize that assertions on the part played by sexuality in the aetiology of the neuroses cannot count upon meeting with the

drama by Hebbel about the sort of person who disturbs the sleep of the world and is hated accordingly; he came to the conclusion that he was one of them. When I was a psychiatrist in the British Army I was rash enough to suggest that the psychiatrists were administering drugs to their patients in order to have an undisturbed night.

O: It is still done.

B: I can well believe it – it has a great tradition, a great past and, I suspect, a very promising future.

Q: Aren't there certain interpretations which serve the same purpose?

B: Yes, exactly. Freud talks about a 'paramnesia' as being an invention which is intended to fill the space where a fact ought to be. But is one right to assume that a paramnesia is an activity which is peculiar only to patients and to pathological existence? I think psychoanalysis could be a way of blocking the gap of our ignorance about ourselves, although my impression is that it is more. We can produce a fine structure of theory in the hope that it will block up the hole for ever so that we shall never need to learn anything more about ourselves either as people or organizations.

Q: Would you elaborate on that? Most of us have built our professions round the extension of knowledge. Now you suggest that the methods we are using and our endeavours are to block our search for knowledge: I would like to know how.

B: I suggest that we cannot be sure that these theories, which are so convenient and which make us – both as individuals and as a group – feel better because they appear to make an inroad into this enormous area of ignorance, are therefore final. One would like to say, "Thus far and no further", but if one carries on this same procedure then one is back again in contact with this vast area of ignorance. With care we can learn the laws of chemistry and physics and feel that *now* we know how the physical world operates; *now* we know the truth. But in fact the area in which the sort of physics and chemistry which we can comprehend applies, is extremely limited. Astronomers have discovered what they call a 'black hole' to which

---

same kind of treatment as other communications. I understood that from now onwards I was one of those who have 'disturbed the sleep of the world', as Hebbel says, and that I could not reckon upon objectivity and tolerance"(Freud, 1914d). This is a reference to Kandaules' words to Gyges in Hebbel's 1856 *Gyges und sein Ring*, Act V, Scene 1. *Ed.*]

the laws of physics and chemistry do not apply. Indeed, the way in which the universe works is beyond our comprehension. Why not? We are ephemeral creatures; our little earth circles round an ordinary sun at the relatively leisurely speed of twenty-two miles a second. No one can imagine the rate of circulation of a spiral nebula around its centre although it is given a comforting and convincingly scientific appearance by saying that the rate of circulation of this spiral nebula, of which our sun is a part, has a diameter of something like 2 × 108 million light years.[1]

Q: Are you then asking whether we are any more aware of scientific usefulness in terms of the state of man's knowledge of the mind? In other words, we are at the point of transition?

B: I am impressed by the short, precise and exact diagnosis which is summed up by saying "Homo sapiens". It is a self-inflicted decoration.

Q: Do you mean that we fill our lack of knowledge or uncertainty with a kind of codified meta-psychology?

B: I would say so.

Q: Theodore Reich used to tell us about what he called, "the courage not to understand". And, in spite of all the remarkably complex and meaningful theories that you yourself have developed in your writings, you are aware, and want us to be aware, of how limited our understanding is. If we can cope with that, and help our patients to cope with that, we are indeed accomplishing a great deal and that is a great part of psychoanalysis.

B: I think it also helps to scale down our expectations of what we think we can do. Over and over again we measure our failures against a standard which is inappropriately high.

Q: Are you also saying that we are made in such a way that by nature we hate freedom? When you say we have to hate analysis because we are confronted with the patient who wears his id on the outside and the ego and super-ego tucked away, that we can't stand to be confronted with that, and if we were wiser we would follow the lead of the id –

B: No, but I suggest that somebody here should, instead of writing a book called "The Interpretation of Dreams", write a book called "The Interpretation of Facts", translating them into dream

---

[1]See also discussion in Talk 1.

language – not just as a perverse exercise, but in order to get a two-way traffic.

Q: Is thinking so painful to us because we do not have the courage to face the limits of what there is to be understood by it?

B: No, I think it is because 'thinking' is a new function of living matter. I do not want to suggest though that some plants have no minds, because we don't know what sort of mind a vegetable mind is – for example, Venus's Fly Trap (Muscipula).

3

Bion: I want to stress an on-going question which seems to me to be of the greatest importance. By 'on-going question' I mean that it has no permanent answer; it is always open. It is a good thing for an analyst to ask himself from time to time why he is doing analysis and whether he means to be doing it tomorrow and the day after that and so on. One gets into a habit of taking it for granted that one has decided to be an analyst, to be one for life as if it were a closed question; whereas I think it is important that it should remain an open question. {In analytic practice the precise instance of the general question is afforded by the decision to continue or to stop an analysis.}

The emergence of this problem requires careful thought by the analyst as to how he is to broach it to the analysand; only he can tell what language to talk and how to formulate, "What do you come for?"; "What do you expect?"; "What do you think I am going to do?"

There are numerous answers: The patient has been advised to come; or recommended to you; or heard about you. It doesn't tell you a thing – it is a superficial reply. But there remains the open-ended question – why has this patient, who has come to you for three years, four years, five years, three weeks or three sessions, come again today? You may have an idea why he came to you yesterday, but that is not today. You can have a constantly changing opinion under the impact of the experience which goes on happening; therefore to treat it as if it were a closed subject does not leave room for development.

Q: Would you go as far as to ask the question, "What am I getting out of this analysis for me? – never mind an outsider".

B: Everybody goes that distance anyway. We don't like to admit it because it doesn't sound altogether respectable to say, for example, that I am here because I get something out of it; or I am an analyst because so far it has seemed to be rewarding. But basically one *has* to consider this. If you are practising medicine you may, like John Hunter, expose yourself to infection with disastrous results. In analysis how wise is one to expose oneself to this emotional experience? Am I going to have a breakdown as the result of the emotional force to which I am exposing myself by setting up as an analyst? Shall I be robust, healthy enough to be able to stand the strain?

Q: What about the other side of that? Is there anything curative for the doctor who helps the patient?

B: There is no chance of knowing that unless the doctor allows himself to be aware that he is concerned with what *he* gets out of it. He may have an urge to be helpful to his fellow men. In that case he does get something out of being a doctor and running the risk of catching the complaints. But he may not appreciate that that is a necessary component and is, therefore, subjected to that powerful emotional situation without having considered whether he wants to help anybody. This is putting it in extreme terms; it is never as clear-cut as that. In time something begins to impinge; you become aware of some dis-satisfaction; the dis-satisfaction accumulates and has no outlet.

O: For a number of years Kleinian theory was not acceptable to many circles in New York City. Now there is a lot of acceptance, but there is considerable conflict in psychoanalytic techniques; the more classical group adheres, or has until very recently, to a much stricter definition of the transference; they don't make the same kind of early interpretations; they are less in touch with psychic processes. I wondered if you would share with us some of your thoughts on these differences.

B: I have not been particularly aware of differing from any other analyst. I *have* been aware of not knowing as much about psychoanalysis as I would like; that is brought home to me both in talking with another analyst and comparing his ideas with mine, and also by my patients who constantly demonstrate that I don't know a great deal of the subject. But this is not in any way different from any other kind of human suffering; people learn that it is painful to continue to

live; they have anxieties of all kinds and they want some assistance. A great number of people go so far as to get married without considering what they mean to get out of it –

O: This goes for Kleinians as well as Freudians –

B: I think so – it is easy to say, "I'm married". You can get a licence, you can get the State to support you in this idea. In analysis you can call yourself, "a Kleinian" or, "a Freudian"; whether it means anything is another matter.

O: Your uncertainty is reflective of what we all feel many times. But in psychoanalytic literature we are often struck by the kind of certainty which is almost foreign to our personal experience; references to the breast, the penis, the penis inside the mother, and all the kinds of things that don't sound nearly as uncertain as you do right now.

B: You have to try to make clear what you are talking about. A definition which avoids being vague becomes dogmatic; it is a matter of judgement. If a patient says to me, "I don't know what you mean", I say, "If you assume that I don't mean what I say, the problem arises as to what I *do* mean". To answer the question by a further elaboration risks distortion of what I, as analyst, have said as clearly as I could.

O: There is something I am struggling to understand – your notion that the analyst empty himself of memory and desire. One way I do understand it is in terms of trying to make myself as receptive as possible to what the patient is trying to communicate to me, but in terms of the way I work it seems to me that my own memories and desires play an important part in my understanding of what my patients are saying to me. I feel that I am caught up in a paradox.

B: {In this respect I agree with you: It is to avoid the distortion of the effects of one's own past history that analysts are supposed to be analysed. In practice it means that one 'consciously' attempts to exclude one's memories, hence rid oneself of memory; for the same reason one needs 'consciously' to exclude desire. When we have not been analysed, or are tired, the obtrusion of memories and desires becomes a liability.} The more one is occupied with what one wants to happen and with what happened, or what one knows about the patient or psychoanalysis, the less space is left for uncertainty. If I become more and more dogmatic, and more and more sure that the patient said this, that or the other to me last time, I know I must be getting tired. When we are tired we find it difficult to be receptive. The actor has to learn to articulate so that he is audible at the beginning

and at the end of a performance: The analyst has to be receptive and sensitive at the end of the session as well as at the beginning.

It is easy to fall into the comfortable feeling that one knows a great deal about the subject and that the patient thinks so too; it is a contract which is made. I am reminded of a rhyme about two famous Oxford historians – Freeman and Stubbs:

Stubbs butters Freeman, Freeman butters Stubbs,
Each ladling butter from his respective tub.

O: I thought, as you were talking, that what matters to the patient is that his 'self' has to come to life, has to be augmented and expressed, so that by this emptying out of expectations and memories the analyst leaves room for the patient.

B: That is so. A patient may say, "I had a terrifying dream last night". This is said so quickly that it almost passes notice. "Terrifying" dreams, "terrifying" experiences – we hear it over and over again. But if you are sensitive you may begin to feel that there is something about it which is beyond just an ordinary statement. There are feelings which patients themselves slide over; they don't want to tell you how terrified they are and how unpleasant it is. If they do get to the point of admitting that, the chances are that they will say, "I was all right until I came to see you, but since then I have been terrified; I get frightened of almost anything I have to do". Of course you are not trying to frighten the patient; but you are trying to make him aware of the fact that he has that feeling of terror. A certain type of patient slides over many remarks inviting you not to pay attention to them and agreeing that they have made progress, are so much better. The next thing you hear is that the patient has committed suicide. The feelings have been of such intensity that while passing off the phrase, "I had a terrifying dream", he does not allow you or himself to know how appalling these feelings are.

What do you see when the patient comes into your room? Usually a mature individual, articulate and much like everybody else: The patient sees much the same. He has heard this psychoanalytic jargon anyway and has got used to the fact that it doesn't mean a thing. So he naturally assumes that the analyst does not mean what he says. But the analyst has to be aware that the patient *does* mean what he says, although he may say it very softly indeed. We should not allow ourselves to be too dominated by the noise that the patient makes – "When I was coming here today I saw an accident in the

street . . .". That is perfectly true, but the noisy way that spectacle can be described by the patient makes it difficult to hear these other noises which are not being made so clearly. {It is the 'forgotten' – 'unconscious', 'repressed' but nonetheless active experience which has been re-awoken by the immediate stimulus of the accident; at the same time the immediate experience has been reinforced by the 'forgotten' element.}

So – you have to have your senses wide open to all kinds of hidden characteristics. Most people don't see what is the matter with a colourless person, but a doctor ought to be able to see that this indicates an anaemic condition. There is something about the colourlessness of the patient which is more than ordinary everyday pallor. This applies equally to what the analyst sees and hears of the patient.

O: There is a difference in the Kleinian culture; maybe interpretations are more cryptic or more related to your own perception than hooking into what is happening from the patient. A certain orientation may put a slant on your interpretations.

B: Of course it does. That is one reason why I say it is necessary to denude oneself of memory and desire.

O: The Kleinians say that one uses one's own phantasy therapeutically – one's own counter-transference reaction, all of one's reactions to the patient, and some kind of unconscious communication between the patient and the analyst.

B: I am very happy that the Kleinians do that; if that is what they like doing that's fine by me. But it is no good to me.

Q: Could you tell us about yourself then – how you work?

B: I am doing so.

O: You mentioned to me recently that when you and Melanie Klein were involved together you made quite a strong condition that you were your own person when it came to thinking and reacting – that this was a very important condition in establishing relationship.

B: Yes; she said she was prepared to agree, to put up with it. I don't think this was particularly acceptable, because she wanted to make it clear that when she said the infant evacuates parts of its personality it doesn't want, and shoves them into another person, she meant just that. She did not want it supposed that that was not her opinion. There is the dilemma: She had to be dogmatic enough to say, "That is my opinion; it is an omnipotent phantasy". But I don't

feel that what I am exposed to in my office is just a phantasy of the patient's.

There can be millions of rational explanations; the patient can say things which are so exasperating that you get annoyed and angry. That could be said to be splitting-off their feelings of hostility and putting them into the analyst. But perhaps it is not so simple as that; perhaps something really takes place when two people are so closely associated as they are in a psychoanalytic experience. If these elements don't exist what is the good of doing psychoanalysis anyway? If we are simply conversing like anybody else, why call it a psychoanalysis? Why put up with years of sessions about nothing in particular? There must be some reality corresponding to this 'meaningless' term 'psychoanalysis'. It is just an invention; a verbal noise – but I think it has been invented because something exists which has to be given a name.

Q: On the one hand there is something steadfast about the description you are providing of yourself in working with the patient despite what you call an open and emptied mind. On the other hand there is a notion of some kind of change or growth that takes place in you along with the patient. Would you comment about that apparent contradiction? My other question is, can you see yourself learning about counter-transference reaction from your patients?

B: Taking your second question first: My understanding of the correct meaning of the term 'counter-transference' is that it is *unconscious*[1]; since it is unconscious, the analyst does not know what it is. So I have to put up with the fact; it is to be hoped that I am aware

---

[1]See discussion of the language of transference and countertransference in Talk 1. [See also *Experiences in Groups and Other Papers*: ". . . many interpretations, and amongst them the most important, have to be made on the strength of the analyst's own emotional reactions. It is my belief that these reactions are dependent on the fact that the analyst in the group is at the receiving end of what Melanie Klein (1946) has called projective identification, and that this mechanism plays a very important role in groups. Now the experience of counter-transference appears to me to have quite a distinct quality that should enable the analyst to differentiate the occasion when he is the object of a projective identification from the occasion when he is not. The analyst feels he is being manipulated so as to be playing a part, no matter how difficult to recognize, in somebody else's phantasy – or he would do if it were not for what in recollection I can only call a temporary loss of insight, a sense of experiencing strong feelings and at the same time a belief that their existence is quite adequately justified by the objective situation without recourse to recondite explanation of their causation" (Volume IV, p. 213). *Ed.*]

that I have there elements about which I can do nothing unless I go to an analyst myself and get them dealt with. It is a question of making the best of a bad job. The bad job happens to be me. I cannot get thoroughly analysed – I don't think there is such a thing. It has to stop some day; after that I have to make the best I can of who I am.

In answer to your first question: Supposing we were really steadfast, one would wonder what was the matter with us. Time passes, we grow older, and if our ideas remain the same there must be something wrong. It is much more likely that we fail to notice the change that is taking place in us; the actual work that we do, whether it is organizing a shop, or being a doctor or surgeon or analyst, has an effect on us. It may not be at all clear what it is. When you were young, grown-ups said, "How you have grown!"; they stood you against the wall, marked the height, and there! There's proof that you had grown. But if the child is in fact 'growing up' we cannot stand that personality against the wall and mark its growth.

O: I had the impression from a seminar of Donald Meltzer's I once attended that Melanie Klein gave off interpretative remarks almost constantly, and that these were in the order of ruminations – she ruminated out loud.

B: I would not have called them ruminations, but I think that she did give a constant stream of interpretations. Latterly, I would have thought that they were too coloured by a wish to defend the accuracy of her theories, so that she lost sight of the fact that what she was supposed to be doing was interpreting the phenomenon with which she was presented.

Q: You have observed the patient; he is there in the room with you; you have some impression; you must make the decision to communicate it or keep it to yourself. How do you deal with that question?

B: I have to act 'on the spur of the moment' as we call it; you are spurred by the moment. You decide not to say what you think you observe, and the patient doesn't turn up again. Or you *do* say it and the patient thinks, "I'm not going to a person who tells me these alarmist stories; of course he wants me to come for an analysis; of course he has a vested interest in making money out of patients, and naturally he would tell me I need an analysis". So, on the spur of the moment you have to react. It would be surprising

indeed if you felt that your reaction did not leave a great deal to be desired.

Q: Is it always an obstruction if the analyst, in addition to having an impression, thinks conceptually about the ego state, the state of resistances, the degree of symbiosis or individuation that this patient is marching towards in terms of libido – and so on? Do you see these primarily as concepts that obscure and fool us into thinking that we know more than we do? Or are these working hypotheses ever of value?

B: I think they are quite useful for about three sessions – if you are lucky enough to see the patient on three successive occasions. You know nothing whatever about the patient and therefore have to formulate some sort of theoretical opinion – the theories in that instance taking the place of facts, because there are no facts. After that you hope not to allow your theoretical preoccupations to obscure the impressions to which you should be exposing yourself. This is not easy to do – there would be something seriously wrong with your patient if he couldn't make a fool of you. At the same time there is something seriously wrong with the analyst who cannot allow himself to be made a fool of; if you can tolerate it, if you can tolerate being angry, then you may learn something. Never mind about all these theories of what analysts *ought* to be; what we ought to be is a matter of no importance in the *practice* of psychoanalysis or in the practice of any part of real life. It does matter what we are.

O: I am disturbed about the issue concerning counter-transference. In the last fifteen or twenty years some of us have come to realize that what used to be something that one was to consider himself guilty for experiencing and acting out with a patient, is a human experience that occurs in the patient-therapist relationship related to the therapist's past. In *Second Thoughts* I noted that you referred to counter-transference a number of times as if you believe in it as a theoretical concept. What I want to get to now is process rather than theory. If I react strongly to a patient I may, after reflection, feel that I over-reacted and ask myself, "Who does this patient remind me of? I seem to be allergic to something in our relationship that is triggered in my being with her at this moment and I then intellectually, through memory and feeling and other associations, realize that in some way she does indeed remind me of my sister from an earlier period of my life".

Ordinarily I would then conclude that I have been experiencing a counter-transferential reaction and have displayed some evidence of this in my over-reaction – or what I now believe to have been an overreaction. What seemed to have been helpful to me I might – or might not – then share with my patient, depending on how appropriate I felt it to be. This I label my 'counter-transference', and perhaps might then use it more openly in the future in my work with this patient. You say this is an unconscious experience which, because it is unconscious as it occurs, is therefore unavailable and not particularly of value; in a sense you discard it. I am troubled by that.

B: I would say that while you are with the patient there is nothing you can do about it. But, thanks to what you have been saying, when you consider the matter afterwards you can decide – and this I do think is possible – that your reaction was something which would fall into the category of counter-transference.[1] In that way you have a chance of learning something about *you* – it is one of the 'fringe benefits' of being an analyst.

O: I am interested in your concept of the container which fits into some of the different views of counter-transference. The previous questioner was talking about the more classical view of counter-transference, something from our own past that we transfer onto the patient. I think the Kleinian view is that the patient induces in us certain reactions; good and bad aspects of the self are split off and projected into the analyst, and the analyst is thereby induced into feeling and behaving in certain ways. Many analysts are totally unaware of the kind of counter-transference the Kleinians talk

---

[1][In Freud's original sense. Expressed in a letter to Jung, 7 June 1909 (in McGuire, 1974, pp. 230–232), in which he referred to the dangers for the analyst, and the patient, of countertransference impulses arising in the analyst as a result of being disturbed by what, inside himself, was evoked by unanalysed correspondences in his own mental life with elements of the patient's. In hinting at the potential usefulness of such feelings, if acknowledged and harnessed to the task, he showed the same genius with which he had salvaged his concept of transference from being a major obstruction to analysis into its being recognised fully as the medium for analytic change. "Such experiences, though painful, are necessary and hard to avoid. Without them we cannot really know life and what we are dealing with. . . . They help us to develop the thick skin we need and to dominate 'countertransference', which is after all a permanent problem for us; they teach us to displace our own affects to best advantage. They are a 'blessing in disguise'". *Ed.*]

about. Some of the newer concepts of counter-transference are useless. Instead of sitting there and suffering and getting angry with the patient it would be viewed as a way of actually boring the analyst, dehumanizing the analyst, deadening the analyst, keeping him at a distance. The reaction of the analyst can be used in a therapeutic way; in fact some of the modern thinkers in psychoanalysis feel that the counter-transference may be the most valuable thing in the analysis; they feel that the negative therapeutic reaction comes out of this kind of negative counter-transference more than any other factor in analysis.

B: If it doesn't come into analysis there is something wrong with analysis. We are extremely dangerous animals; of all the ferocious animals that inhabit this earth the human being has succeeded in killing off all rivals – except the virus. At the end of the First World War the 'flu epidemic killed off far more people than had been killed in the war. For all our wonderful destructiveness we are nothing like as efficient as the virus.

In the analytic session one is concerned with two dangerous and ferocious animals, one of whom – and possibly both – has at the same time a wish to be friendly and helpful to the other. Parents retain an impulse to continue to be helpful to their children even after they have sent them off to earn their own living. In the analytic situation we are not usually dealing with a blood relation but with a mind which is very like our own. I think one is under an obligation to remain civilized, but remaining civilized is not the same thing as being unaware of what human character is really like.

We are concerned with powerful impulses which are anything but civilized – murder, hate, love, rivalry. So we have to be sensitive and aware of the powerful emotional nature of the two objects in the same room at the same time – as well as this element which wants to be helpful. Even the hostile patient would like to be helpful to the analyst and turn the analysis into an everlasting one so that he doesn't have to find any more friends – he just sticks to the one in the office.

We are faced with a paradox; we are struggling both to retain such civilized capacity as we are capable of and at the same time to make evident the primitive and dangerous nature of the situation.

Q: If you were too civilized might you be destroyed by the patient?

B: Yes. Translating Kant's statement[1] into the kind of thing we are familiar with, the individual is intuitive but doesn't match it with any concepts. If Kleinian theory has anything to do with the real facts infants must be marvellous Kleinians because they know all about what it *feels* like, but they have no concepts, they cannot write any of these great books – their concepts are blind. Later on they have forgotten what it is like to feel terrified; they pick up these words but the words are empty – "I'm terrified". You have to notice that it is an empty phrase, it is a concept; it is only verbal; the intuition is missing. If we can draw attention to this fact then possibly the *concept* of terror and the *feeling* could be married. The analytic procedure is an attempt to introduce the patient to who he is, because whether he likes it or not that is a marriage which is going to last as long as he lives. When the patient talks about terror he really knows what he is talking about. It is useless for the analyst to talk about some psychoanalytic theory unless he can say, "*This* is it".}

O: You said every infant is a Kleinian: I wondered if it is also true to say that every Kleinian is an infant.

B: Yes, absolutely – but unfortunately grown-up, and they look exactly like adults. We all have this illusion that we are adults, we have reached the peak, and have nothing more to learn. That is why I suggest asking this question which is open-ended – Why am I doing analysis?

O: I want to offer an assertion and ask your opinion of it. I have come to the conclusion that one of the analytic myths that we tell our students is the *incognito* of the analyst. I think such a thing does not exist. I had a discussion some time ago with a colleague; I said, "Everyone knows that the patient is plugged into the analyst, but to the same extent the analyst is plugged into the patient". In other words, the patient knows as much about the analyst as the analyst knows about the patient. Of course the difference lies in what each of them does with it; the concepts of transference and counter-transference are gimmicks which help us to conceptualize something, but are no help beyond that.

B: {I am materially in agreement. I would not, however, describe transference and counter-transference as 'gimmicks' but concepts

---

[1]See Talk 2: "Intuition without concept is blind; concept without intuition is empty".

formulating illuminating observations which Freud made. It is the reality behind those concepts with which we, who practise, have to work.[1]}

O: I have been thinking of your work, *Experiences in Groups*; I wondered if I saw happening right here in this room the dependence assumption. Everyone was saying, "Teach us; show us; you know; your thinking, your brilliance" –

B: Not to mention the pressure to believe one is equally brilliant oneself.

O: Yes, as well as the audience. But what happens in reaction to the frustration when the dependence assumption isn't gratified?

O: I wasn't sure whether you were answering questions or making interpretations.

B: They are all interpretations of impressions; an impression which I get, which I expose myself to and then translate into verbal terms. But in this respect I am dependent on my sensory apparatus and on my capacity to interpret what my senses tell me.

O: I also felt you were interpreting instead of answering our questions. I was wondering whether this is the way you actually function with a patient, using your own perceptions –

O: Like the use of yourself as the diamond that receives and reflects back (p. 243).

Q: Is your discussion about the embryo in fact a discussion of where we are?

B: Analogically one can say that psychoanalysis itself is at its birth, so we don't know much about it or this peculiar, unpredictable development – growing up. That can be unpleasant; even the analyst can feel, "I don't like being aware of this universe in which I live".

After the First World War everybody decided that the Western Powers had won and that now we were in for a very good time – all would be well. Santayana wrote that the Great War was not an aberration, from which we had now got back to normal happiness and good health, but that it was an hors d'oeuvre, which ushered in the *return* to the normal state of affairs – fighting, destruction, rivalry, hatred.

Q: You have often said there is so much about analysis that we don't understand; I have the same feeling. Would you tell us about

---

[1][Added later. It is not clear what was Bion's spoken response at the time – if any. *Ed.*]

a current case in which you feel you don't know what is going on; what you are doing with it or thinking about it; how you are trying to understand it?

B: The patient said, "I had an awful dream; I dreamed I was swimming and I suddenly discovered that the stream was carrying me straight through a weir; I was going to get sucked in and destroyed. I tell you I never woke up so quick in my life." That is a curious statement. Ordinarily you would think that if you were swimming and found yourself in that situation you would get out of the stream. But it is peculiar to say that this is such a terrifying dream that "I tell you, I never woke up so quick in my life". It takes some sorting out because it is not the way in which I am used to talking, and it is not the way in which I am used to thinking either. The extraordinary thing is that this particular patient has always succeeded in earning a living and has been married and had a family. So there must be something which is right about it; there must be something about that way of thinking which I don't understand but which must be useful. I would like to know what it is. I have thought about that plenty of times – I am not much nearer to understanding it.

There are other situations which are similar. It is difficult to communicate to you the factual situation. The patient said – as near as I can reproduce it – "I'm awful. I got through these exams, but I don't know a thing about it – not a thing". That was about the end of the facts. The rest of the session was taken up in a conversation which would appear to be a link between the patient and myself because we were using ordinary words. But there was no idea of who the patient was, and no idea of who I was – only the link in between. That is a queer conversation; that is a conversation in which – putting it into mathematical terms – there are plus signs, minus signs, signs intending to mean division, division of X by Y, but no mention of what X and Y are or what the two sums are that are to be added or subtracted.

Q: Are you saying that you couldn't tell from the patient's conversation why he said these things to you?

B: I had no idea. First of all I would want to know what the language was – it's not mathematics. It appears to be American or English; it *appears* to be, but it isn't. I could say it is a matter of semantics; it is not. I could say this is a language in which a sentence is composed of conjunctions only. But this conversation does seem to have an

effect; the patient keeps on coming to the sessions and I continue to agree to see him. But how that is brought about I do not know.

I said to the patient, "You haven't yet told my why you come here."

"I haven't told you why I come here? I am doing nothing but" says the patient. I can only assume that the patient is correct; why it has passed me by I do not know.

Q: How does the patient react to learning from you that you haven't the foggiest notion why he is there despite his belief that he has made repeated efforts so to communicate? What does that do to the patient to learn that you are confused?

B: {If the patient had 'learned that I was confused' they would not have been listening to what I said. "I do not know" is not the same as "I am confused". I might be confused or angry or frightened, but those are private matters which I consider to be irrelevant. I do not mind the patient 'analysing' me, but in fact he has come to be analysed. It is important if *he* is confused or angry or frightened, and it is important that I should make him aware of that. It is wasting his time to tell him what my troubles might be – those are matters for myself and my analyst.}

Q: Do you think the patient doesn't want you to know what is going on?

B: I think the patient wants me to know and expects me to know. I am obtruding an irrelevancy if I behave as if I do not understand what he means as if I were irritated or bored. The trouble is that I am frightened of being ignorant of what is going on.

Q: To come back to the statement of the patient, "I got through the exam but I've no idea how". I take it from what you said that you didn't do anything with that statement; what followed was a senseless or not understood dialogue. Was it based on that statement? Or did you ignore the statement? Did the statement do anything to you?

B: I drew attention to the fact that the patient was not talking a language I understood; therefore I was not receiving the communication.

Q: You did not make an attempt to get what was behind that message?

B: Yes, I did, because it seemed to me to be a highly dangerous situation.

Q: And in a case like this you would not follow the traditional procedure of analysis and ask the patient for associations to it?

B: Yes, as soon as I am tired I do exactly that, I say, "Thank God for the accepted procedure".

Q: I would like to clarify what you said about the 'evidence' for the truth of an interpretation.

B: I am prepared to accept the theory which scientists put forward about this. It is what I call 'apodictic' proof, facts which are inescapable. They are forced upon you; something happens which forces you to accept it as the proof of the previous controversial matter. However, this is complicated by Heisenberg's Uncertainty Principle. If the physicists cannot say what a fact is, then this ignorance and the disappearance of certainty is liable to spread.

O: I had in mind the experience where there is a sudden evidence of the truth.

B: Yes, something convinces us that what has been said is illuminating.[1] But what that is a proof of is another matter. I don't think one can say that it has much to do with facts except facts about the human animal as it is now; there are certain experiences we have which carry conviction.

Q: In *Learning from Experience* you talk about thought disorder and about modifying an experience rather than thinking. Does that tie in with the description you gave of the patient who was talking on and on and you couldn't find the link?

B: The link, I am convinced, is not articulate speech; it is something else. Sooner or later someone who is exposed to the experience I have been talking about may be able to formulate this peculiar kind of 'umbilical cord' as a method of communication between the two people. I could say that this type of conversation is like a breast which might connect an infant with a thing which turns out to have a mother stuck on the other end of it, so the breast and the mouth come together. That is all very well as analogy, as a pictorial image of what is going on, but what is the 'thing' that is going on? If one could climb down the DNA helix to a point in infancy, perhaps one would be able to know. But if one climbs up and reaches the same point, only on a different level on the helix, what is it this time when there is no mouth, no breast, but this peculiar conversation which is

[1]See mention, in Talk 1, of Prince Andrei, *War and Peace.*

nevertheless effective? Since the patient is talking to me and using his language I ought to be able to be receptive to it; I ought to be capable of hearing this communication and of knowing that the patient has told me what they come for. As the patient says, why don't I know?

Q: Couldn't you be effective just by your presence, by being a container, or a battery charger?

B: Possibly. Why does one have to know? I feel pressure to know because I think it is dangerous not to. I may be in trouble if I cannot understand what the connection is between somebody or something not me and what I consider to be me.

O: Winnicott talks about the analytic situation which is similar to transitional objects where the omnipotent phantasy of the child is reinforced by the responsiveness of the mother. It is the responsiveness of the analyst trying to know what the patient wants, of the experience of somebody being tuned in to him, that is unique to the analytic situation for many patients.

B: This is a useful idea if you are old enough and intelligent enough to be able to talk English in that kind of way. If the patient is falling back on a method of awareness which was available when he was an embryo being communicated with through a watery medium, then it may be obvious to the patient *how* there is a contact – but not so to me. It is important to be aware that the relationship between the two things – the patient and myself – is only transitional, a transient experience. It is as well to consider that a word like 'transference' has shades of meaning which are applicable, like 'transience'; it is only temporary, the moment at which the two paths cross for a short space of time during which a method of communication is employed by the patient which I am able to receive but do not know how it is done. I would, however, like to be able to verbalize it; I would like to be able to put it into some language – painting, music or mathematics.

{The patient that I described as saying that he had got through an exam but did not know how, showed by his constant repetition of that state of mind that the important matter was not conveyed by the ordinary meaning of the words, but was conveyed by the monotonous reiteration. In short, I can only describe it as a 'musical' contribution. That 'music' eventually became clear to me and I was able to give him an interpretation of what it was that he was conveying.}

4

Observation: I have been thinking about the opportunity I had with a patient who came back after seventeen years. I got a call; she asked me whether I remembered her – I really didn't, but I remembered the name. The thing I have been pondering is that this lady told me that for all these seventeen years she had been holding on to something I had said; it was a kind of magic. What interested me was that I don't think I ever said it; it doesn't sound like me at all. It was, "There is no law that you have to stand in line with his bullet". I may have talked about her relationship to her sadistic husband, that she had the right not to take the kind of sadism she was expected to, but it was the wording that interested me – I don't think it was mine. There was such gratitude and magic in this. She returned because she hoped I could again come forth with a phrase for this poor suffering soul. She had had an awful life. A child of hers had been killed by a fall in an elevator shaft – partly due to her husband's carelessness in leaving doors open in his own factory; and her older son died of a horrible cancer. The first time I saw her, her first words were, "I have a few little problems", and out came this horrendous account. It was Dr Bion's speaking about language as a communication which interested me; you don't often have a patient coming back and telling you what they think happened. Did I say it unconsciously? Did she hear something, or did she make this up? How does one know? Or doesn't it matter?

Bion: We all have to get used to an extraordinary thing; this queer conversation, which we call psychoanalysis, works – it is unbelievable, but it does. The result is that you give various interpretations which you may or may not remember. It is difficult to believe that you may nevertheless have sown an idea which has germinated and

given birth to still other ideas until the patient comes back and tells you ideas which she thinks – and probably quite rightly – she got from you.

But you don't recognize them because you haven't seen what has happened since you sowed that particular seed in her mind. If you had a son or daughter who went away for seventeen years you might be surprised at the physical resemblance that person had to yourself and take a moment or two before you realized that in fact it was your son or daughter – similarly with ideas. So I wouldn't in any case be particularly disturbed by the discovery that some idea sown during that previous contact has germinated and come out in the form she can recognize; after all, it has grown in her and not in you.

{What matters is that a patient establishes the psychoanalytic ritual of so many sessions a week, so many weeks a year and so on. The origin of the ritual may be difficult to trace; thus peculiarly distressing circumstances, about which nothing can be done, are a fruitful source of omnipotence, omniscience and omnificence. So, it is likely that this patient would want to believe that the analyst was a beneficent power which she could adore; this would require interpretation. The analyst could fall into the mistake of accepting the proffered omnipotence, or alternatively of ignoring the *fact* of the help she had given. Patients do not come back for nothing. The analyst has to establish what is relevant and what is not. This implies a standard of Truth. In practice truth can only truly be described as an aspiration which may be beyond the capacity of the human mind.}

Q: Could you elaborate on a distinction you made between 'good and bad' and 'good and evil'?

B: {The Nazi ability to organize the Nuremberg Rallies was 'good'; the use to which it was put is a matter of opinion. In my opinion it was 'evil'. It is important for the patient to know what is *his* opinion. To conceptualize the difference would require an ability to discriminate between the moral and the technical.}

Q: I have re-read your paper on *Memory and Desire*. In it you say the psychoanalyst should forget the patient has a past and a future in relationship to him. I don't think you mean that as concretely and specifically as it is stated in that paper. Could you elaborate further on that?

B: I have to use this new-fangled trick of human speech which is only a few thousand years old; I have to use words which are

extremely crude and exaggerated, black and white. As far as the meaning is concerned they are not only black and white; they are often so fuzzy it is hardly possible to make sense out of them. We try to pull this faculty in the direction of doing something for which it is not intended, namely, the investigation of the human mind. So we put forward these statements and hope that the individual reader will be able to turn them into sense of some practical kind.

Q: Could you give an example in clinical practice of how one can suspend memory in working with a patient? Is there a technical device for that?

B: When I feel a pressure – for example, "I'd better get prepared in case you ask me some questions" – I say, "To hell with it; I'm not going to look up this stuff in Freud or anywhere else, or even in my past statement – I'll put up with it". But of course I am asking you to put up with it too – an impromptu affair of this sort. With regard to your patient you could say, "Surely I ought to look up the notes on this case. Oughtn't I to have made some notes on what this patient said to me? What would happen if the patient ran me into court for malpractice on the grounds that I hadn't prepared notes, that I didn't even remember what I had said before?" I can well see that you would get an unfortunate experience out of trying to explain in a court of law that you had not in fact done it because you don't think it works very well. It is much easier to believe that you don't do it because it is so nice to be lazy, not to worry with these things, to enjoy life instead. It is, oddly enough, difficult *not* to do; I should be very surprised indeed if, towards the end of the day or week, anybody resisted the pressure to drag up some psychoanalytic theory rather than go on not having the faintest idea of what the patient is saying or doing. But tomorrow is not today; and if tomorrow is seventeen years later – as we have just heard – we may not even recognize the face of the patient or what the patient said, and feel guilty about being greeted as if we had done something helpful. Unfortunately we tend to feel that our ideas aren't worth preserving so we are liable to lose touch with them. The patient who returned after so many years may have discovered that what you had to say was a great deal more valuable than you realized.

Q: Does it matter whether I said it or not?

B: It is hard to say. We think it matters whether we analyse people or not; whether it *is* worth doing is a different matter. The spoken

word certainly seems to be powerful. Tacitus gives a description of the behaviour of the bards amongst the German tribes who used to recite to the tribe, and from its reaction they would tell whether it was safe to proceed to war or not. The function of the bard could be called diagnostic; the function of the leader can be to try his seductive songs of war or murder on his audience. But does this mean that it is of use for us to talk to other people about 'the self'? It would be of considerable use if we could mobilize a meeting on the scale of the Nuremberg Rallies; it seems to me that we have to assess this matter of the efficacy of human speech against the background of history so far.

Q: When the child or the patient evacuates does a vestige remain? I am thinking of the infant who cries – feeling unpleasure or hunger – evacuating into the mother. I cannot imagine that child losing that feeling of unpleasure.

B: Partly because the evacuation takes longer than is supposed. In other words, the child has to do what it 'thinks' is an evacuation – it has got rid of these nasty feelings and ideas. {The 'vestige' remains, but has a power like that of a wound which festers.}

I get the impression that even the person who has dealt with the problem in that way has a feeling that something has taken place which must be kept out. So, once you have got rid of the unpleasant feeling, idea, proto-idea, primordial idea, keep it out. It doesn't seem to be far from what Freud said, that the repressed has to be kept repressed, except that I would reinforce this now by saying, the 'evacuated' has to be kept evacuated; it has never been unconscious. Some different word from 'repressed' or 'suppressed' is required for elements in the mind which have never been conscious *at any time* – and that means they have never been unconscious either.

Q: Would the term 'non-conscious' do?

B: If you find the term 'non-conscious' serves your purpose I certainly think you should retain it in your vocabulary. I find it easier to consider the existence of thoughts without a thinker. It has been put rather differently by Pirandello as the title of a play: *Six Characters in Search of an Author*. But why stop at that? Why should it not be something which is even smaller, more fragmentary than that? It is a thought wandering around for some thinker to lodge itself in.

Q: You don't want old language, you would rather find things without connotations?

B: I have tried to use them in this way: There can be certain things which we would nowadays call thoughts or ideas but which are really physical. I am dubious about using terms like 'the adrenals' and 'the optic thalamus' when I am talking about the mind. I shall never know whether there is any such thing or not, but I think it is convenient to leave one or two boxes empty in case somebody is able to fill them up. Similarly with regard to these diagnoses which are floating around – leave them unattached till somebody pulls them down to marry them with their proper origin.

O: You used the word 'evacuation' first as a kind of synonym of projective identification; later it appeared to depart slightly from the meaning of that term. I wondered if you could draw a distinction between the two. To me it seems that evacuation is a much more radical process than projective identification.

B: It is more radical because it is more concrete. But as soon as one starts giving words a more concrete meaning they become even more distorted. Or you can leave it up in the stratosphere of intellectualization – 'projective identification'. Melanie Klein herself said it was a bad name – it is.

O: Hanna Segal said that you have explained it pretty well and applied it clinically more than anyone else.

B: It may be because of the advantage of being analysed by Melanie Klein and having the experience of being told, "You are doing it".

Q: What is the difference between identification and projective identification?

B: {'Identification' should be kept to mean what Freud said it meant. Similarly, 'projective identification' should be kept for occasions when the occasion itself – as observed by the analyst – seems to fit in with an interpretation which the analyst thinks is better expressed by Melanie Klein than it would be by words of his own.}

The foetus has no choice but to get born, and is forced out into harsh gaseous fluid instead of a nice watery fluid. And similarly we have no choice except to communicate our interpretations by virtue of the gas – air – which we use or abuse for phonation.

Q: Is water always better than gas?

B: Not always, because the foetus is clever enough to take a little of the watery fluid in the nasal channels. The result is that it is still able to breathe and to smell. Smell travels very well in a watery fluid;

it is a long-distance receptor. Fish can smell decaying matter from a distance of many miles.

Q: Do you think the foetus can smell in the womb?

B: Yes, but that is an imaginative conjecture; I have no evidence for which I could claim a scientist's validity.

Q: Obviously the question of language is a very difficult one. But if we are going to discourage the use of words hitherto familiar, but already empty of meaning, how are we to talk to each other.

B: I cannot see any alternative to disagreement and discussion amongst psychoanalysts who know what the problem is to which they want to draw attention.

O: I would like to germinate the idea of thought without a thinker.[1] I thought of Lewis Carroll, who dealt with this concept easily: The Cheshire Cat – the smile without the cat. Then I thought of Edward Lear – wonderful so-called 'nonsense' poetry, which might have more sense than any other poetry because it has its own unfilled language. I feel that Doctor Bion too wants to make this unfilled language, and I can sympathize. I have great doubts of how much can be used of the existing language and the habit of human thinking. I think a two-and-a-half or three-year old can be better analysed than an obsessive intellectual adult, who has every word defined and comes to analysis to learn about himself. I find that kind of very bright patient particularly hard to deal with. Are there people you deal with who still have a balanced enough mind to think new thoughts? What do you do with this idea of thoughts without thinkers?

B: If they were our thoughts we might be able to do something about them. But since I am trying to define the possibility of thoughts *without* a thinker, I am talking about things which are not within my capacity and which may not yet have found a lodgement in me.

{The importance of the last speaker's comments cannot be exaggerated. Her own example may save the child from the worst excesses of the modern 'Babel'; the child analyst's position is onerous and exciting.}

O: We have two polarities: At birth the possibility of germination and the possibility that we can have a baby; then we have all these

---

[1][Francesca Bion reports that Bion felt at the time that this contribution to the discussion was 'right on the button', as he put it. *Ed.*]

images of catastrophe, war, storms and terror. This seems to be the implication you are making.

B: You can regard birth and death as being extremely important, but they are not diseases. Nevertheless there is such a thing as maternal mortality; there is such a thing as infant mortality; and there is such a thing as death for people who are old. The result is that these apparent conjunctions make people think that they are therefore synonymous. It is important that one should see a distinction. Of course that itself is a slanted view, a view that we should learn how to talk articulate speech. *Our* concern is with the interval between birth and death and the need to know how to use articulate speech in our work.

O: There is a phrase that I read in a paper by you about the psychotic and non-psychotic aspects of the personality that has intrigued me. I have never seen it used anywhere else and I don't think you explained it at great length in the paper; it was "the furniture of dreams".

B: {We 'furnish' dreams with what we remember as pictorial images. What they really are will have to be determined by practising analysts.} It is true; one is always leaving these loose ends for the simple reason that one knows so little and one's life is so limited. Even mental capacity fades too fast to be able to carry these things through. One hopes that some phrase of the kind you mention can turn out, in the hands of somebody else, to achieve a meaning which could be useful.

O: Almost like a thought in search of a thinker.

B: Yes. But where did you get that idea? You could try to label the owner, the originator, the creator, but I think you would soon find you could not. For all you know it may even be you; you can be the storm centre of your own storm.

You may be originating something without being aware of the fact. This survival from the past about possessions – my this, my that, my idea – seems to me to be nonsensical, although I can well understand why someone like Melanie Klein can be irritated if she finds that the ideas or theories she produced are debased and devalued. One would like to have some respect for the ideas and keep them in their original bright working order. To do that you may have to invent the language you have to speak while you are speaking it.

Q: And hope to be understood?

B: I think that is being a bit greedy. The luxury of hoping means that you have first of all to hope that you have not been talking nonsense and that there is somebody else who is able to make sense of it. In this respect we are almost like cell bodies ourselves; there could be an idea floating around without a lodging place, without having found an appropriate cell sufficiently distorted for it to lodge in.

O: Children in play therapy, finding something is painful, frequently feel it has something to do with the air. They may blow bubbles, make aeroplanes.

B: I suppose children's games are fun for a time, but then the children begin to quarrel or get bored – which I think is the same thing as getting frightened. What is frightening about a game of fathers and mothers with dolls? As analysts we begin to suspect that these games are not 'just games'.

The child goes off to the mother or father and says, "What shall I do now? I can't think of anything to do" – the game has become intolerable. Later on, when individuals are not playing fathers and mothers, but are actually being parents, they have forgotten the fun element and so this 'game' becomes so terrifying an occupation that they want to rush off to God or Devil or Psychoanalyst and say, "What game shall I play now?" What game are they to play if the thing which is not in fact a game at all, but which might have been both the real thing *and* fun, hasn't worked out?

The fact that people can say "this is not working out" means that there is some hope for it; perhaps something better is being found. But as long as people draw a well-patterned coverlet over the games they get on with underneath, they will dislike having the coverlet removed. I don't think we can be sure that people won't get so frightened that they say, "Let's have it all back again – it may be humbug, it may be lying, it may be deceit, but at least it is more comfortable than this factual world you are inviting us to face".

Q: What about the reality of *our* group at the moment? How is everyone reacting? What is happening here under the coverlet?

O: I don't feel all that terrible emotion some people are hinting at. I think Doctor Bion is extremely demanding of us and I find that very stimulating.

O: I feel a sense of dissatisfaction and restlessness.

O: I feel fascinated.

O: I think one of the feelings of uneasiness is connected with language. We are talking in the tradition of German/American/English. This afternoon I was reading a paper by a French analyst and this evening I was thinking how psychoanalytic theories must feel different in different languages. We, as Americans, do not have the investment in our words that French people have; we have a different way of talking to each other and of talking about the things we experience with our patients. I am wondering if a lot of the unease has to do with shifting into completely different gears. We are used to talking a kind of shorthand to each other and there is something about the proceedings here which is reminding us that we are talking shorthand.

O: I recall at the conference at Topeka in 1976 on Borderline Disorders the contrast between the way in which psychoanalysis was talked about by the European analysts and the American analysts. It seemed to me that American psychoanalysis is more akin to baseball than it is to European psychoanalysis.

O: Yes, we are not philosophic, poetical, historical; we are more technical. That is the way we are used to talking to each other.

O: That may be a fault.

B: It is possible that the genuine Americans still retain an experience of what it is like to live in a strange and dangerous world in which warmth and food are not obviously forthcoming unless you produce them. In that way you can have it forcibly brought home to you that even the matter of food is not to be taken for granted unless somebody does some work for it. Although you succeed in being so successful that living becomes comfortable – houses, central heating, electricity and so on – there can remain a rooted remnant of awareness of the fact that life is not really like that. It can look almost like a kind of schizophrenia: On the one hand you have a culture, a capacity for thought, which has lost and forgotten the primitive base; on the other hand there is this remnant, vestige of an awareness of the reality of things.

That seems to me to produce something which is as near to a synthesis as to become noticeable. You produce wonderful physicists, chemists, Nobel prize winners, but there remains that highly active vestige – roughness, violence.

In Europe it broke out; there had to be a 'Great War' to make

people aware of these thick layers of hypocrisy which are difficult to penetrate without a most painful birth process.

{This discussion here is the prototype of what American civilization might do to make the violence – of which we are all aware – redundant.}

Today there may be some quarrel going on between the 'thinking' done by the body and that done at the cranial end. There is some hope that in spite of the fact that we all have diaphragms they are not purely non-permeable membranes; we hope that they do move up and down and do in fact have a lot to do with continued life. So maybe there is something analogous to mental movement by which the two are mingled. The representative of a trade union suddenly discovers the charms of being the boss and becomes 'cultured' – but what culture is that? Does he then become completely divorced from these 'inferior, lower class' people who work with their hands? One hopes that the diaphragm will be more likely to mingle the two than to cut them in two halves that do not re-join. The situation requires more than a conjuror or his tricks. As analysts we try to elaborate a technique for ministering to a mind diseased, razing out the rooted trouble; it is an unpopular occupation. {Being analyst or analysand is hard; no one who is not robust need apply. It is not safe to be unaware of the danger.}

O: The term 'projective identification' implies the continuing contact between one and the other. Evacuation does not imply that.

B: Melanie Klein said that patients *think* they evacuate something: that they have the *phantasy* that they have got rid of this chunk of themselves into the breast or the mother, although it only sounds like words, the sort of thing you puff out of your mouth. If a chimpanzee shows its hostility by making a rude noise with its lips it can have an effect on the baby chimpanzee it is trying to silence. The question is, to what do you attach importance – the flatus, the gaseous flatus you evacuate through your lips, or the noise you make in doing so? When does cacophony turn into music? When do these rude noises which you make with the aid of instruments like bassoons and tubas – and even with your mouth – become beautiful music? Or wonderful ideas? When do rude noises masquerade as profound thoughts?

O: It sounds as if the distinction has something to do with the nature of the product. Projective identification always implied to me

a product that had more completeness, wholeness and structure than the fragments you talk about as 'bizarre objects'.

B: There is a great advantage in its having some material quality. You can say, "black man" or "white man": there you are: you don't have to do any further thinking; they have arrived completely coloured and correctly labelled. So why waste time going through all this fatigue and nonsense about thinking about him or her or it or them? Why not deal with it according to the colour which has so mercifully been provided so one can tell which is which without thinking?

O: The point is, how you feel about 'black'; how you feel about 'white'; and what kind of emotional reactions we have for the black and white. I will try at the same time that I attack you to defend you too. You are talking in general about no-man's land – which of course is true. We don't know what a thought is; we can describe it, but we don't *know* it. That is what you are doing all the time. But if we want to talk about what affect it has or what impact it has, to use it in a practical way, then we have to do it somewhat differently. From time to time I can grasp what you are saying; I think there could be an original idea. And then you talk on with almost dissociated ideas, making big jumps – what we are thinking, or what goes on in the universe or the atmosphere – and then I get lost. Until all of a sudden you make an excellent remark and something could come out of it – and then I get lost again.

O: That is what Doctor Bion attempts to do. I don't blame him for not being more clear because in essence nobody can be more clear about the things we discuss.

B: I agree with you. One of the few situations in which we can defend ourselves is when we can say that what we feel is a *fact*; I think it is about as near to a fact as we are likely to get. The patient can say, "I know for a fact what it feels like to be me, and to feel what I feel when I sit in this room with others or by myself. That I know; that I am satisfied is a fact. All the rest of it is theory – psychoanalytic theories, French theories, English theories, black theories, white theories, any colour you like to mention". It is awkward if a Newton says that 'white light' is really made up of a number of colours. There's an intellectualization for you!

Q: That bastardizes the feeling of black and white – it makes everything more complicated and confused?

B: Certainly. If you say that that black person, or that white person is in fact a human being, that really mucks up the whole thing; that means that somebody has to do some thinking. You are thrown back on this horrible occupation of thinking.

O: You haven't talked about the Grid.

B: As soon as I had got the Grid out of my system I could see how inadequate it is. {"He put in his thumb and pulled out a plum, And said 'What a good boy am I![1]'" But the satisfaction does not last for long. As a pictorial model I suggest the boy sucking his thumb, pulling it out of his mouth to examine it with admiration, but in time becoming dissatisfied. What I experience is that 'theme with variations'.}

Q: Is it not workable?

B: {It is for you to decide whether it is any use to *you*. If it is not, do not waste time on it. The same advice applies to any future Grid that I might formulate.}

Q: Is it hard?

B: Not for me – only a waste of time because it doesn't really correspond with the facts I am likely to meet.

Q: How does Melanie Klein's theory of envy as an inborn attribute help us to understand the earliest development of the infant?

B: It probably helps you thanks to the intervention of Elliott Jaques. Having read the book he said to Melanie, "You've got the title wrong – it ought to be 'Envy *and Gratitude*'" – *that* she had left out. That book is meaningless unless one also detects the gratitude.

Q: How is it helpful to think about this as a preconception, as something which is innate as opposed to something which is learned?

B: We can use beta-elements and alpha-elements in order to talk, or to provoke an argument, or a train of thought. But before I can translate these bodily sensations into an idea I have to retain some capacity to understand the language my body talks to me. I don't like it because it so often misinforms me. I dislike having things done to me which don't cause me any particular harm but which are appallingly painful. So I would like to get some assistance from the cerebral end of my body which would translate that into a language which was more useful, more comprehensible and more to the point. Assuming that I have to be prey to the body I was born

---

[1]Nursery rhyme: *Little Jack Horner*.

with and to what it persists in telling me, before I can attempt to be articulate and to aspire to these heights of highly intelligent theories, I first have to go through all kinds of unpleasant stages. One of them is what I would call speculative imagination or speculative reason. Unfortunately one has to go through this stage when one is extremely vulnerable; someone may say, "What rubbish you talk! You have imagined it". True – or dreamed it in a lucky frame of mind. But if one then, under the provocation of being contradicted, says, "It is not just imagination; it is a fact", that is not accurate. The appropriate child of a speculative imagination or speculative reason is a *probability*. The mathematicians think they have formulated a theory of probability. That is not a fact; it is only probable. Somebody who knows some mathematics may be able, thanks to their analytic flair, to elaborate a mathematical theory of probability which is some use.

Q: There must be some use for this idea of inborn envy. How have you found it of use either in the understanding of the infant and the interaction with the mother, or in some way understanding what the patient is going through?

B: A patient to whom I had been giving a prolonged period of interpretations was furious, and burst out in expressions of violent envy and hostility whenever I said something which appeared to be a gratifying discovery about him. I said, "There is one person in this room, at any rate, who is really envious of you, and that is you. When I was rash enough to say that that was a very interesting observation you had made, there was at once a great burst of vituperation, both against me for saying such a thing, and against yourself for having said something which excited attention".

Q: How did the patient react to that?

B: After a time he began to become more tolerable and tolerant. This patient could only wear clothes of a certain colour – no departure from that particular optical wavelength. He had learned to tolerate some clothes enough for purposes of survival provided he stuck to the same clothes which he wore year after year.

Q: What makes that innate?

B: I don't know. I would be inclined to say that somebody's ovum and somebody's spermatozoa had got together and had an intercourse which produced an object which has these striking characteristics. By the time it succeeds in getting born – and hasn't so far at any rate committed murder – there is one person whom nobody

can save and that is the patient from himself. If he wants to murder anybody he is the one victim who is always available at any hour of day or night, and no analyst or parent can intervene between himself and his Self.

5

Question: How do you use the term 'caesura'?

Bion: I would like to have an idea of what this area is which is being delimited when you say "caesura". I was saying just now that I think I can feel when I am in what I call a "capital city", and that I feel New York is one. I don't care what the map says, or what is said by any other place; that is not what I am talking about. I wouldn't like to try to say what a capital city is. So when you ask me about the caesura – and indeed any of these words we use – every one of us needs to be aware of this thing which is the *origin* of the sensation that there is something around. When I say there is something around which I would call a 'capital city', it is no good suggesting I should go and look up the words in a dictionary or a guide book. There is no guide book to the domain or area we are talking about. What then is the 'capital city' of this caesura? What is the core of that? I have been asked this question, but I am trying to put to you that I cannot really tell you because I don't know how it is to be verbalized. Perhaps between us all we might be able to find an approximation to it, some method of indicating the focal point, the focus of a conic section. But that is again only another model; people have tried to give it various names like 'spirit', 'soul', 'super-soul', 'id', 'ego'; they none of them get me very far.

O: Maybe a colloquial reference: 'where it's at', is as good as anything.

B: Yes. A phrase like that conveys something to me. This is what we are up against the whole time: How is this awareness to be communicated to somebody else? Where does this communication start, where is its origin, where or how is it initiated? Did the place initiate

the feeling that it is a capital city, or did the idea or some primordial thing, and a whole lot of those primordial things getting together, produce something for which the name 'capital city' had to be found? It is not the bricks and mortar, but the people in it; then it isn't the people in it, it's the souls inside them. This is the sort of issue you are up against in tomorrow's session.

Q: Is it primordial? If we find a realization which a capital city is it necessarily localized in individuals?

B: I don't think it is so at all. I think it is convenient if it obtrudes to a point where even we notice it. But that is not because I am blind and have only just seen the bricks and mortar. It is something else which obtrudes which makes me feel there is a pressure which I find hard to localize.

If you show a dog a photograph of a little boy it smells it, realizes it can't eat it and that's that. But put the same thing on a movie and project it onto a screen – then the dog gets excited. It is only a photograph but it is a moving photograph and that the dog begins to think has a meaning. We also; there are certain things which set up a vibration. Then we begin to notice something. So if we allow ourselves to be sufficiently sensitive for long enough then we shall begin to feel something impinging on us. We might ultimately find some way of communicating it.

Q: Is psychoanalysis a depth phenomenology?

B: There is a lot to be said for a phrase which was used by Melanie Klein to me; "Psychoanalysis is a meaningless term, but it is available". It is a word in search of a meaning; a thought waiting for a thinker; a concept waiting for a content.

O: It has had many contents.

B: Unfortunately that is true. There is no shortage of material available for mental nourishment, but what the unfortunate mind is stuffed full of we don't know. The amount of rubbish which is lying around for purposes of filling a space is enormous. Freud talks about amnesia as being something which fills a space when you have forgotten what belongs to it. That would be all right if I knew where the pathological ended and the genuine began. It is nice to think, "Ah, psychoanalysis is *it*; that's what we all need". Do we? Or is it more stuffing? Is it more noises to occupy an empty space? This point can only be decided by those of us who are engaged on that activity we call psychoanalysis for want of a better word.

Poets have found a method of communication: Milton invents a word, 'pandemonium'; Shakespeare strings together ordinary words in a way that starts things vibrating inside countless generations of people. Why? How is it done?

Q: Are you suggesting that not only do we need to invent the language but we need to be more poetic in writing about the things we discuss?

B: No. I think the central point is that you need to dare to be available to something you want to express; to dare to allow a thought without a thinker to lodge somewhere in the range of your capacity. It might be to make marks on paper; it might be to make marks on stone; or it might be the capacity to set electro-magnetic waves moving. In other words, a person writes a bassoon concerto; if somebody else is clever enough to be able to play the bassoon, and to translate various black marks on white paper into sound waves, then that communication spreads if there is anybody around prepared to listen. The artist is dependent on the off-chance that someone will listen or dare to turn himself into a receptor. The patient is dependent on the analyst being sensitive to the faint signals which he cannot make louder. But in turning ourselves into receptors we are taking a big risk. From what we know of the universe we live in some of the information may be most unwelcome; the sound or signal we receive may not be of the kind that we want to interpret, to diagnose, to try to pierce through to this 'thing' behind.

{A real poet is able to use language that is penetrating and durable. I would like to be able to use language that did the same.}

O: I am interested in the process of communication or dialogue, or lack of it, which goes on in this group. I have a feeling that maybe you want to make us continuously realize what it feels like when there is no communication between us and you. But whatever you say is always fascinating; I'm not sorry I came; it's nice to listen. I am simply hurt, insulted that you offer us dialogue and we don't have dialogue. You let us know – and I know that anyway – the shortcomings of language, the dangers of feeling concepts prematurely, the necessity to leave the characters wandering alone before we conceptualize, define. But nevertheless human language isn't that bad; you cannot think it is that bad – you write a lot and we all enjoy reading it. So you certainly know how to use language. Today someone

threw in the idea of 'caesura' – without aggression, without asking for a definition, just to play around with it. But you didn't react to it; you play around with the idea of why one cannot define anything. I wouldn't mind if you had come and said, "Let's have no dialogue; I'll just talk". That's fine too; I love to listen to you.

B: It is unfortunate that in the situation you describe, instead of being able to develop the possibility, my own personality obtruded. {If you are right the dialogue has been spoiled by me, and you are right to feel that it could be better done by somebody else.} I try to give you a chance to fill the gap left by me. Perhaps tomorrow in our sessions each one of us may be able to learn something which I have *not* been able to tell you.

O: It seems to me that what happens in this room is something which happens in our offices with equanimity with certain patients. We do not gratify their questions; we give them something they can use which is – as you were saying earlier – planting the seed for germination. I particularly appreciate that you are not so explicit because it gives me a chance to get in on my own thinking and my own development.

O: Everybody is interested but there is some strange wish to mystify things for which human language would be adequate.

O: I have a different feeling – although I have felt exasperated at times too by not being able to focus in the way I wished. The sense I am getting from Doctor Bion is that he is so aware of how concepts can be misused and concretized and become part of the luggage that gets in the way, that in justice he misreads his own concepts which many of us have found very useful. We might misuse them, true.

O: He doesn't suggest that you misuse them; he suggests you might put them to better use than he does.

O: Yes, but if we try to deal with any one concept, that concept is already no good.

O: It seems to me that Doctor Bion's purpose is to help us to think differently and that he doesn't feel that ordinary dialogue is useful.

O: If that is true then we shouldn't be asked to ask questions. Let's say we just sit here and listen to whatever Doctor Bion says – but don't ask any questions.

O: Then he won't be able to have his effect.

B: I plead that by my actual presence I am behaving as if I did think there was something to be said for dialogue and even for getting together – conversing if possible. But at the same time I don't want to mislead you into supposing that my characteristics, whatever they are, are therefore necessarily desirable. You may indeed have to overcome that particular hurdle in order to get to the real truth behind it. The central thing is this: In my experience there is a real truth behind this debate; although I have not got there myself, somebody else may. Plato's dialogues have provoked thought amongst people who weren't even in existence when he originally engaged in them.

O: In the last few days I have thought back to some splits that have come out and have been troubled over them – I have not been so stimulated in a very, very long time. Maybe we are just expressing the pain of being made to think.

B: There is a certain redeeming quality about it all; we can still retain a hope that somebody, sometime – perhaps now – will do better than our Selves. I know my limitations up to a point. There are plenty of opportunities for me to learn about all my faults and mistakes; they are uninteresting, and they are a nuisance. Nevertheless one hopes, somewhat optimistically, that in any given community there will be people who can do better. If you have a family of your own you hope that it at least will avoid most of the blunders the parents have made.

O: I am a bit mystified by something that I sense going on amongst the group. I don't understand everybody's readiness to agree that we are non-thinking people. As a group we have talked to each other about exciting ideas over tea, over meetings, before patient, after patients till midnight. We are not stultified, ironclad; I don't know what kind of model we are setting up to say we shouldn't be.

O: I would like to take it back to the beginning, to my question about the caesura. I think Doctor Bion answered my question very well. It was taken out of context; it was an idea that occurred to me after the discussion about intra-uterine existence and the problems of the foetus.[1] I was wondering what Doctor Bion meant by caesura in that context. I have no complaint about the way he answered this question. Perhaps now that we understand that this was good enough we can go on from there.

---

[1]See Talk 2.

Q: Don't you think that many of us feel a great deal of frustration?

O: I don't like anybody to speak for me. I find Doctor Bion most inspiring and I think I understood some things. So I have no quarrel at all with the way he handled it.

B: My difficulty is that I have to borrow words from the past; but the past is finished, there's nothing we can do about it –

O: We can understand it –

B: But I have to use that vocabulary and unfortunately, as you rightly remark, we understand it. What I am trying to point out is something we *don't* understand. I am going to use this model, but I want to warn you that it is only a model and it is liable to obscure more than it illuminates. There is such a thing as the birth of an idea; I suggest that it is a most uncomfortable experience. Whether it is a group of people or an individual which is giving birth to an idea the pains which are associated with that experience are extremely upsetting and disturbing, and somebody will certainly try to put a stop to it; nobody likes pain. I think it would be rash to assume that this problem is only within this room. We feel that the individual is unique and deserves to be given a chance to blossom, to grow, to develop, and for there to be a space in which to do that – whether it is an individual person surrounded by a skin, or whether it is an idea which is much more difficult to recognize. I should be surprised – again falling back on anatomy and physiology – if the phagocytes do not collect and try to gobble up this new idea before it gets more troublesome, before it turns into a contagion or an infection. It may not be a pathological idea and its destruction could therefore be unfortunate. That seems to be the magnitude of the problem which faces each person here or in the office. We can consider and debate these matters; it would be a great pity if we didn't dare to do so. Physicists and chemists can draw this wonderful diagram of the DNA molecule but they have not defined the difference between the animate and the inanimate. *We* are sure that there is one. A table seems to be different from the things that we are. Defining it may be a matter of little importance but I am sure that there are feelings, embryonic ideas, primordial ideas which deserve to have a chance of development. I do not know whether they will turn out to be good or bad; somebody has to have the courage to say, "Even if the child I give birth to is a monster I'll risk it".

O: It would require a very strong person.

B: Yes, and there may be little willingness to admit the strength of such a person. It can be assumed that anybody can give birth to a child or to an idea – it's so easy. Then there's trouble when you find it isn't easy. I see no reason, for example, for believing that the psychoanalytic movement will not be stamped out at any time by government, an authority, something which has power behind it. But I don't see why we should therefore be intimidated and refrain from psychoanalysis.

O: I think we have many phagocytes in this city that are always, as you point out, gathering to make sure that a stillbirth occurs. It is difficult under those circumstances to produce an idea that is not only new but which will survive long enough to become threatening.

B: I talk about white blood cells, using this pictorial language – it is a verbal form of pictorial imagery. There are people who are impatient of the restraints of verbal communication and find other methods. Valéry said that it is assumed that the poet is a person who is undisciplined, disordered, goes into a rhapsodic state and emerges, wakes up with a poem complete in his mind as the outcome of an undisciplined, intoxicated – literally and metaphorically – state of mind. Valéry believed that, on the contrary, the poet is much nearer to an algebraic mathematician than to an intoxicated individual.

O: Coleridge would say, "Weave a circle round him thrice . . ."[1]

B: These issues are involved in seeing your patient tomorrow – the one that you haven't seen so far. Even if it is one you think you saw anatomically yesterday or last week or last year, it is not the one you see tomorrow.

O: Could you give us some hint as to how we could see that patient in a way we haven't seen him before; how to suspend any memory of having had contact with that patient. I have been attempting to do that and it is very difficult. The patient's name is in my appointment book so I can't eradicate it from my future unless I am going to do away with my appointment book.

B: It is indeed difficult to say how to denude one's mind of preconceptions, memories and desires which make such a noise that one cannot hear the patient speak – at least not the one that we need to hear speak. In my experience the noise of my past has so many echoes

---

[1]Samuel Taylor Coleridge, *Kubla Khan.*

and reverberations that it is difficult to know whether I am really listening to the patient or being distracted by one of these ghosts of the past. I have had the experience of seeing a young adolescent and thinking to myself, "It's very queer; he hardly says anything, but he sits there with that silly grin on his face". I couldn't think that it reminded me of. The next morning when I was shaving I saw it in the mirror – that's why it was so familiar. This young man was supposed to be an adolescent; he wasn't supposed to be the analyst; he wasn't supposed to be teaching me anything. I was supposed to be analysing *him*. But in fact he had held a mirror in which I could see my face – but I didn't recognize it.

Q: What did it teach you about the adolescent?

B: It taught me that I had better try to forget these painfully acquired ideas about psychiatry, psychoanalysis, psychotherapy and the rest of the luggage which I was carting around with me; it interfered. If I had only been able to see at the time, I might have been able to make some contribution which was helpful.

Q: Like what?

B: I don't know – I never made it. I lost the patient at the first interview – and he was quite right.

Q: If you could speculate, if you had understood what you understood next day, what might you have done?

B: I can't say, because I cannot now draw upon the actual information which I might have been able to use at the time, had I been open to what was being made available by this patient. In other words, the analytic session is priceless; the potentiality of the analytic session – the direct emotional experience – is out of reach almost as far as value is concerned.

What other people are prepared to tell you about the patient is worthless compared with what the patient tells you – maybe verbally, maybe dramatically, maybe mimetically.

O: What you are saying then is that you capture the thing-in-itself by isolating it in the analytic session. But it seems to me to be very difficult to be able to capture the thing-in-itself if you don't have the necessary training.

B: That is one of the big difficulties. As Freud put it, you have to know where to look, where the apparition will appear – literally. I am not talking about a ghost; the thing that appears does appear.

You need to have your senses directed towards it. Then when you begin to feel something you might close in and focus on the point of irritation – using the term in the neurological sense of nerve irritation.

{J. M. Barrie led his audience to expect the appearance of Mary Rose at a stage entrance towards which the whole cast directed its gaze. By this means the actress was enabled to enter unobserved. With the raising of the lights came the illusion that a spirit – not a physical body – had been present.}

O: It seems to me that this 'baggage' we bring with us is akin to a character-honouring that prevents a kind of neuro-perception.

B: Yes, it is possible.

O: It can be baggage that interferes with communication, or it can be wisdom that facilitates it and magnifies the possibility of having an experience. You can't say that theory is baggage.

B: No, but it turns into baggage. My wife asked me. "What shall we take to New York?" –

O: You had very little luggage!

B: "The temperature is 80 today – yesterday it was 40. Which lot shall we take?" You see; it is as simple as that. But when it comes to a question of mental baggage, that really is a problem. I believe that on the whole the kind of psychoanalytic baggage I have collected is more of an asset than a liability; what is left by the time I have mobilized it seems to be more valuable than what I have discarded or what I have forgotten. But only time can tell; unfortunately it is unlikely that we shall live long enough to know the truth.

O: While with a patient my mind wandered briefly to a personal preoccupation. The patient said he felt disconnected. I don't think I had made a sound, but I know his feeling was related to my thinking about myself. I don't understand it.

B: The impression I get is that this is a fundamental, primordial characteristic. I don't think it is acquired through reading books or meeting people or having a lot of experience of life. Even the infant is aware of feelings of dependence *and* isolation. Grammatically there is no difficulty in describing it – "I was all alone in the room with so and- so". But we attach very little importance to those words. It is only on looking at it more closely, only if you bring to bear our psychoanalytic microscope, that it turns out that that commonplace phrase has a meaning that most people aren't aware of. I think you can be stirred to the depths by something which seems to be so

insignificant that it is hardly noticeable; it is probably lost in depths of knowledge so that this spark of insight gets swallowed up.

Q: Is there an association between your recommendation that one eschew memory and desire, and the notion of abstinence that Freud used as applied to the analyst?

B: I would have thought that they are fairly closely associated. Melanie Klein used to say she wasn't a 'Kleinian' analyst, she was just a psychoanalyst working along the same lines as Freud. But whether she liked it or not she was condemned to be a 'Kleinian'. So, with reference to your question, one would like to be able to acknowledge one's indebtedness without insulting the person from whom one says one has borrowed the idea.

O: The other similarity I thought I saw was in the recommendations that Freud makes in *The Interpretation of Dreams* of how one should approach the dream without preconceptions.

B: This is so; I don't think it is distorting what he said. We hope to quieten down our internal noises so as to hear what is being said. It is difficult to combine this with the use of knowledge or experience which other people have made available. It is the difference between actually living life and theorising about it.

O: When we live life we also feel that – I think Kant was right – we cannot know the thing-in-itself. There is always something in human perception which is already there. Children say, "We cannot crawl out of our bag". We try at least to crawl out as much as we can, but only if we keep in mind that we actually *cannot,* shall we get relatively as close as possible. One questioner sounded as if he would have taken you literally, not as a *façon de parler*, saying, "If I look at my appointment book I know the name, I know who the patient is". Of course one has memory; of course if I go from here to there I have a theory of laws of motion. One cannot do anything without an implied theory. We might want to talk metaphorically to give an intense feeling, or we might want to spell it out. But we shall be a little closer to knowing the thing-in-itself if we point out that we cannot know it.

B: One has to dare to go through various preliminary stages before one reaches even a theory. That is what I meant when I talked about daring to exercise your speculative imagination and your speculative reason; the place which one would like to occupy with facts is taken by probabilities – probability, using it in the sense I understand Kant to use it, as being something for which the facts are inadequate.

It might turn into a fact later; there might be enough evidence to justify saying, "I know if for a fact". But what we have to deal with are situations which are stimulated literally on the spur of the moment.

O: We all live by our theories whether we know it or spell it out or not. Most of us live by the theory that ghosts or poltergeists are not around. I am aware of that because I have a patient at present for whom it is absolutely natural to believe that poltergeists exist. She is a daughter of a poltergeist-layer, so she grew up with the attitude, "Daddy has a poltergeist today"; like, "Daddy has a new patient" – there will be money coming in. Her assumption is that if the curtain moves someone was here – no fright, nothing; just about the same theory as I expect this chair will not fly away. Maybe there are poltergeists; she might be right; it is a probability.

B: I can have theories about babies and even about what babies think, but babies don't have to have theories about it – they think. I can imagine – again indulging in speculative imagination – that at some point the baby begins to suspect that behind the food and the seat which carries it around there is an actual person. But there is no language for it; you have to wait before you call the thing "Mother" or "Father".

O: I always thought a baby called it an 'object'!

B: It probably did – if you could translate it back again into the original language.

Q: Why wouldn't the first experience of what is known be a 'being'? Psychic experience is non-sensuous – how could it be a 'thing'?

B: I can imagine noises of something rushing through my cranium, or thumps taking place somewhere inside; and I can imagine that I might be suspicious that some 'thing' had got inside me. The baby cannot make use of articulate speech so there is a big gap between the baby who knows the facts and we who know the language. One can identify oneself with the person who potentially is capable of articulate speech; one can also – or so it seems to me – retain some ghostly characteristics which know things unknown to me, but which are not verbalized. All that my body says is, "I've got a pain". It isn't very informative; it is not much more informative than somebody on the road using their horn – it doesn't tell you much. You cannot interpret that into movements of your feet and hands which will activate the clutch and brakes.

O: I would like you to say something about hate. You were talking about events prior to knowledge, on the way to being knowledge; I was confused because you said that events which are not yet knowledge are probable. And hate is something absolute.

B: {When I speak of 'absolute hate' I refer to one pole of love; there cannot be darkness without light.}

Q: In your article about the psychotic and non-psychotic parts of the personality you described the feeling of anxiety when your patient told you he was going to attack you. Could you describe that feeling? Is this a common occurrence?

B: It is quite common enough for me not to like it, and common enough for me to have automatic methods of being aware of it. I do manage to keep in good working order an established defensive system. From that point of view I automatically defend myself against feelings and experiences and people who start stirring up some disagreeable feeling. At the same time I am also trying to understand what is going on. So one is at war with oneself in this respect; one is at war with one's natural defences.

Q: When you described the feeling in this article you said it was following your interpretation that this patient tried to put into you the fear of the attack; that the patient then clenched his fist so that you could see the whites of the knuckles. Did your interpretation make him angry?

B: Certainly. It is one reason why we would be somewhat optimistic to suppose that the analyst and the analysand did anything which exempted them from hating psychoanalysis. We are perpetually, by our own activity, stirring up the hatred of this occupation in both people. But we mutilate our Selves if we become incapable of feelings of hate as well as feelings of love. The problem is how to avoid auto-mutilation and at the same time not to mutilate these tender, growing shoots of civilized conduct.

O: I think all analysts wonder whether the development of psychoanalysis this century is a good thing for the world or not. It is so painful.

B: Yes, it is.

Q: Could you elaborate on what you said about analysts hating themselves as analysts?

B: There is no shortage of enemies – external and internal. So on the whole one regards it as redundant to create some more. All

right – so far so good perhaps. But the next step is, when do we start defending ourselves and defending a position which we may not have decided is defensible – like standing up for psychoanalysis, maintaining the right to practise psychoanalysis before we have had a chance to make up our own minds in some really convincing way that we have supporting evidence for its value?

Q: How about defending the right to make up our own minds?

B: It's a nice idea; otherwise we would have to consider the possibility that our minds are made up for us by forces about which we know nothing. We do want to defend this idea; we do want to defend the occupation of trying to investigate our ability to make up our own minds.

O: I worked once with a psychotic patient who came to me when he was about thirty five; he had been in treatment since he was twenty. His greatest *idée fixe* was a sentence, "I am not homosexual" – and he wasn't. He could only work at night; in the daytime he couldn't be on the street. He worked in a kitchen in a nightclub and there he accumulated all the notes the waiters left around to make sure that he had not automatically written, "I am not homosexual". After many years he asked if he could bring me those notes – that was about fifteen years ago. He became better and started to have a normal life, worked during the day and started to talk to people. Altogether he became more alive and very circular in his phantasies. I suggested that maybe we could stop.

His other *idée fixe* was that he wanted to hold a woman in his arms; he wanted to be able to love a woman and be married. He said he knew he could grow, and he did indeed become better and better. I blamed myself for having almost given up on this man.

When he was in his fifties he met a woman in his office, a divorcée with two sons, and fell in love. I couldn't believe it. I kept thinking, "Why did I think this man couldn't do it?" He married her and although he had never attempted sex with either man or woman, after a few weeks he functioned and loved it. They were married at Easter and planned to go to Italy for the summer. When I came back from my summer vacation he didn't show up for his first session. I thought, "Ha, he is doing so well he is forgetting me – fine". The next session he didn't come. I called up his office. He had had a heart attack and died.

I wondered, did he work himself up to a way of life for which the frame, the machinery was absent? Does it matter that he died? He died with his widow surviving him, not like a homosexual, so maybe it was worthwhile. What was this whole story about? I don't know. Did he benefit from thirty five years of treatment.

Q: What you are saying is, did you kill him?

O: I wondered of course.

O: He did the growing and he did the dying.

Q: Did you think he would live for ever after you had cured him?

O: He was only fifty six when he died.

Q: Is it possible that he somehow linked love with death – when he blossomed in love he was closer to death?

O: The widow called me and said, "I know my husband saw you for a while before we got married". She added, "Fairy tales don't last long – it was a fairy tale, it was so beautiful".

B: I remember a primitive Maori discussing a matter of this kind; he said, "Is man a stone that he should live for ever?" If people embark on this rash venture as animate objects then they are going to die.

O: I came to that conclusion too.

O: Maybe this is connected with the hatred of being an analyst. Most people have a pretty good idea of what they do or don't do in their work; we can never know.

Q: Your question is, did you help him, or did you help him to death?

O: Yes.

O: You can never know – which makes it rough.

Q: What difference does it make since death is a part of life?

O: True. He had a few very happy months.

Q: Would it have been better for him to live to be seventy?

B: I find myself struck by the toughness of what we call 'conscience'. It has been remarked that "conscience makes cowards of us all".[1] So it does. It is one of the really vital bullies which is difficult to bring under any control. For one thing, it is *so* moral. Anybody who poses the free play of morality is by that very fact sinning. In certain

[1]["Thus conscience does make cowards of us all. . . ." – Shakespeare, *Hamlet*, Act 3, Scene 1. *Ed.*]

religions people talk about 'original sin'; Freud talks about 'free-floating guilt'. It has a long history – long before anybody managed to attach an articulate label to it. So you can be reasonably sure that whether you are analysand or analyst you will be a prey to feelings of guilt and can even be set off on a career of crime detection. The individual can spend the whole of his life carrying out penitential exercises, devoting his attention to confessions of sins of one sort and another, and even committing crimes in order to have something to confess.

O: I guess I wanted to confess it.

B: It is a great sin for somebody to enjoy themselves. If he had a few months of happiness – and what is worse, sexual happiness – somebody would be sure to suffer for it; if nobody else, the analyst.

O: The confession helped – I have never told the story before.

Q: Would you say that the Catholic Church's doctrine of original sin is another way of people from past history talking about the burden of guilt that each of us is bound to assume, and that some of these people were just as wise as Freud in perceiving that?

B: The religious people generally have a long history of acquaintance with what is called the 'soul' or the 'spirit'. So it is not at all surprising that the remains of these various past histories are recorded in one form or another. Nor is it surprising that we find ourselves up against this same phenomenon, this same fact of guilt, either experiencing it in oneself or seeing it operating in somebody else.

Q: Would we be human without guilt?

Q: But do we have to have so much?

O: It seems to me that it is more intense than a hundred years ago. The destructiveness we see rampant today is the other side of guilt feelings in terms of aggressive impulses. I am indulging in speculative imagination and just wonder if in the year 2000 or 3000 – assuming there is a world at that time – the phase of the human being will follow the present trend, or whether there can be some kind of change.

B: Couldn't we be vulnerable to the accusation that not only do we continue to exist but we also have aspirations to live a life worth living – which is adding insult to injury! If indeed we are guilty of this aggressive act of actually being animate I don't know who or what we are opposing. I see no reason for believing that the universe in which

we find ourselves is friendly disposed. Locally, on our planet, animate objects exist. But the scientists, with their various space probes, have not yet discovered a sign of life anywhere else – although it is true that they have not even escaped from the solar system.

O: It is like the crime of being born human.

B: Or potentially 'civilized'.

Q: Why do I have such a depressed feeling now?

O: You remember Kurt Eissler's paper (1975) – he doesn't feel that the human animal will survive; man will destroy himself.

O: We shall become an extinct species.

O: It has happened before with many other species.

O: To revert to this stamping out of memory: I know what you mean, and I know you mean something good, but the danger is in taking it too literally. Physiological memory is the genes – they cannot be stamped out.

O: I took it as a metaphor.

O: Yes; but I think we should remember that the physiological memory is there; whether the original sin is there or not, whatever is there – the potential for joy too – we live by our physiological memory.

O: But when we are really absorbed in something we don't have memory.

B: I would like to invent a couple of words to get on with – 'genotypes' and 'genomenes'; meaning by the genomene the birth of a thing which appears, the counterpart of a phenomenon.

Q: A phenotype?

B: A phenotype and a phenomene as a counterpart to a gene.

Q: What does it mean?

B: I don't know – I invented it in the hope that something will come and nest in it; that some loose content which is floating around will find somewhere to lodge.

O: You invented this term in connection with memory and I am struggling to make a connection.

B: I suspect that there is some counterpart of the term 'birth of ideas'; that there is some reason to imagine that these painful experiences which we have are related to the process of giving birth to an idea – or "struggling to make a connection", which is an instance of thinking. An institution, a society of human beings may be unable to survive the birth pangs of an idea – it splits apart. We are undoubtedly

careless with our psychological midwifery. We seem to feel that the thing to do with a new-born idea is to give it a good hard smack.

O: If ideas are pro-order they have a good chance of being accepted. But if the idea announces that there isn't any order – only disorder – that's pretty horrible, even if it is true.

O: The way I understand memory is that it is always a partial aspect of an experience. Forgetting, tossing memory aside, is tossing aside a partial aspect of the experience, but if it is really taken up into the totality then the memory is a living component of the aspect of the larger totality of experience. So this business of genes doesn't enter into it.

O: Didn't Freud say that dreaming is, amongst other things, a way of remembering? Memory has many faces.

B: I would like to suggest that if anybody recognizes the remains, remnants of a culture floating up in the conversation in their office it would be a good thing to drop your shovels and get out your camel hair brushes, and deal with it very carefully so as to delineate the civilization of which it is a remnant, a survival which has become uncovered. I gave the example of the situation where you get nothing but conjunctions with nothing to join them to.[1] The idea which ought to be conjoined by what is floating up in your office is missing.

O: I am bothered by what you said about guilt – that guilt is a terrible thing. I think the terrible thing is psychopathy. Thanks to guilt, there is such a thing as conscience. Melanie Klein speaks of reparation for guilt; Winnicott, of the capacity for concern which comes from guilt. The great danger of what you refer to as 'lying' is that behind all misuse of language there is fundamental psychopathy.

O: You sound as if you are talking about Watergate.

O: No, I'm talking about life.

O: What about the notion of surplus repression in relation to surplus guilt? There is misplaced guilt, inappropriate guilt.

B: Guilt is such a nasty feeling; it hurts so much. And when something hurts you your tendency is to hurt it back again, scratch it out. If your skin starts irritating, scratch it even if you run the risk of producing weals, which are not much better than the original irritation. But somebody, sometime has to dare to investigate this horrible pain. What you are saying does involve the further investigation of

---

[1]See discussion of Links in Talk 3.

the guilt; not saying it does not exist or is not painful, but going on looking at it. Then you might detect psychopathy. It does involve standing up to the guilt of which one is aware. The same thing happens with other emotions; it is no good talking about a brave man when he is avoiding being aware of the danger which he runs; he has to know it is a dangerous situation he is handling. What is known and felt to be dangerous, and is *still* kept in view, seems to me to be real bravery.

O: To be aware of the dangers of psychoanalysis and then to practise it.

B: And go on practising it.

O: It is either heroic or psychopathic!

O: I have always liked the statement of a wise analyst who said, "By the time you know why you got into the practice of psychoanalysis it is too late to get out".

SÃO PAULO
1978

TEN TALKS

INTRODUCTION

These talks, given in April 1978 under the auspices of the São Paulo Psychoanalytical Society, were the third of their kind and took place on consecutive evenings with a week-end break between numbers Five and Six. This is an edited version of spontaneous contributions made by Bion without written notes of any kind. I hope that, in spite of editing necessary for the printed word, I have preserved the essential freshness of his spoken communications.

Francesca Bion

1

Bion: I am not going to talk about psychoanalysis because I assume that everybody here is familiar with the analytic experience. I am convinced that there is no substitute for actually undergoing analysis with an analyst. People are often misled by the fact that we talk in the way which is familiar in ordinary conversation, so that technical psychoanalytic terms like 'Oedipus complex', 'projective identification', 'identification', have almost become part of cultivated speech; it is not understood that it is essential to undergo a psychoanalytic experience. Those who think that they know all the psychoanalytic jargon believe that they can talk just like a psychoanalyst to a patient who comes for help. But 'just like' is not the same thing as 'psychoanalysis'; the result is a great proliferation of different kinds of psychoanalysis, usually 'new and improved' – using those words sarcastically.[1] That kind of treatment evokes a powerful, emotional situation and the so-called psychoanalyst reacts emotionally himself. The further immediate result is that psychoanalysis gradually gets a worse and worse reputation. If this process continues long enough psychoanalysis will not be able to survive. Thus we bear a heavy responsibility. I propose to talk about the problems with which the psychoanalyst has to deal when he is psychoanalysing. Freud was impressed by the motto of Paris – *Fluctuat nec murgitur* – which he translated roughly as "Storm-tossed but not submerged". The person who is a good imitation of a psychoanalyst *is* submerged by the storm he evokes. The more desirable state is a difficult one which I will try to describe like this: The analyst, if he has had a real analysis and

[1][A previously unpublished paper by Bion with the title 'New and Improved' is included in Volume XV. *Ed.*]

training by a real psychoanalytical institute, is a feeling person. So in this stormy turbulence he shares that emotional experience because he is a feeling person. He is also trained to think while amidst these stormy emotions.

Using war as an example: An officer is not supposed to be unaware of a terrifying and dangerous situation; he is nevertheless supposed to be able to go on thinking if he finds himself in a position in which panic, panic fear arises – let me remind you of the god Pan. But he is not supposed to run away. He is supposed, in spite of being in the midst of this emotional storm, to go on thinking clearly. In that way he forms a focus from which the more disciplined reaction will build up; the troops will not run away, but will begin to stand fast.

I use that model deliberately because the situation in the consulting room appears to be so different. It is usually a comfortable room and apparently there is nothing to be frightened of. Yet patients can get up and leave the room and never come back again. The analyst is not supposed to find himself a prey to emotions which cause *him* to leave the room; he is not supposed to be unaware of these powerful feelings, nor is he supposed to stop thinking clearly. Nor is he supposed to be overwhelmed by desires, including sexual ones. This situation is basic, it is fundamental, and although it appears in groups it also appears when there are only two people in the room. One could very nearly express it in biophysical terms, such as the chemical products of the adrenal bodies. When do these chemical reactions become functional in the embryo? When could the embryo be said to feel fear or aggression? I am aware that we cannot hazard a guess without being vulnerable to the accusation that we are simply indulging our imaginations. But I think it is most important that we *should* be able to do so. A patient who has no dreams is also likely to have no imagination; that becomes a significant symptom, a sign which we should recognize. Repeating this slightly differently and referring again to the group: Victor Hugo says, in *Les Légends des Siècles*, that the emotion shared by two opposing armies in war is terror. If you are a member of one army you know that you are terrified; but you imagine that the enemy are all brave and disciplined fighters. In World War I there occurred one Christmas Day a fraternization between the opposed armies. The reason why the troops could fraternize was that they all knew what it was like to be at war. The Staff were somewhat withdrawn from the actual combatant experience,

so they could see that, from a military point of view, to emerge from your trenches and greet the enemy was to give them important information about your numbers and your position. So the Command – on both sides – forbade any further fraternization at all. That experience never occurred again – either in the first World War or in the second; chivalry was killed.

In the shared emotional experience of the analysis the analyst is somewhat in the position of the officer who is obliged to think clearly. It sounds so simple – especially if you have never had an analysis.

I want to turn now to what we, as analysts, should observe in the analytic experience. What are the facts which we are supposed to observe? How do they come to us?

To consider this matter in an academic fashion – in the way in which we can when we are not practising analysis, but are discussing it here – I want to suggest that we do not in fact see or observe what we ordinarily think of as 'facts'.

At first the analyst is ignorant of what is happening; if we are honest we have to admit that we haven't the faintest idea of what is going on. But if we stay, if we don't run away, if we go on observing the patient, after a time, "a pattern will emerge".[1] That is possible when we are concerned with physically sensible facts – in short, all that our senses bring to us. The problem then is, what is our interpretation of the facts which our senses are making available to us? In other words, there has to be what we call an 'interpretation' of what our senses tell us. There is a great deal of what I would call 'evidence' which makes me think that there is such a thing as a mind.

Suppose this word 'mind' is not referring to a figment of the imagination, but to a peculiar kind of 'fact'. Cats and dogs appear to behave as if they have minds; I see no reason for supposing that there is any fundamental change when one of these animals learns the trick of walking on its two back legs, and later calls itself 'Homo Sapiens'. How does that fact – if it is a fact – come over to us who are observing the person? In addition to the evidence which our senses give us there is the evidence which is brought to us not by our sight, but by our *insight*. That is another 'fiction'. So I want to introduce – borrowing from Kant – the idea of *rational conjecture*. I want also to add to that *imaginative conjecture*.

---

[1]Freud quoting Charcot.

When we are waiting for this pattern to emerge we should also be sensitive to our imaginative conjectures and our rational conjectures as a part of the pattern which will perhaps become clearer to a point where we could translate it into words which we would try to communicate to the patient.

Q: My question is in the form of a fable. A scientist had a little fish in an aquarium. One day the little fish jumped out of the aquarium and the scientist observed that it could survive for five minutes. The next day the little fish repeated the feat and was able to survive for ten minutes. A day came when the fish was able to survive outside the water altogether and accompanied the scientist to the cinema, the theatre, everywhere. One day there was a storm and when the scientist went outside into the street with the fish, it fell into a little puddle and drowned. The moral of this fable is: Learning new things, but forgetting what has been learned before, is highly dangerous. Using this model, what would be the implications, in the patient/analyst relationship, if the analyst, while delving into unknown situations, the 'unknowable', gets catastrophically lost and destroys a therapeutic situation?

B: When the patient comes to the consulting room which animal has come? The scientist? Or one of these little creatures we have just been hearing about? And to which are you going to talk? Most patients were familiar with a Kleinian experience when they were infants; but they couldn't tell anybody what that experience was because they had not learnt the language necessary to make interpretations, diagnoses, verbal communications. After many years they acquire a considerable vocabulary but by that time they have forgotten what they wanted to say,[1] so they are as far off from communicating with somebody else as they were when they were full-term foetuses or amphibians, or even leading fishy existences surrounded with amniotic fluid.

There are two people in the consulting room, both of whom are in a peculiar state of mind – the state of mind in which we are when we are awake with our senses about us. That state of mind is different from the one in which we are when we are asleep. We are also in a different state of mind when we move about in a gaseous fluid from

[1]Melanie Klein did not forget. She was able to say it, but by then what she said comes to us as unfamiliar and peculiar.

that in which we are when we exist in a watery medium. I expect you have all seen a new-born baby who can be put on a pot and its bottom seems to know what it is supposed to do. But I am told by psychiatrists that it cannot because its fibres are not myelinated. So I observe an impossible fact; that is the trouble with facts – they are all impossible. If you wrote the true story of your life between the time when you were born and the time now when you are here in this room, and if you were to say there were a lot of other people making a similar journey and that they came together in this room in São Paulo on April 3, 1978, nobody would believe it – everybody would know it was so impossible that it wouldn't be worth reading such rubbish. Similarly with the baby and its non-myelinated fibres – who or what told it what to do when it felt a pot under its bottom? Of course, the baby – to indulge in some more imagination – might decide that it wanted to keep its products to itself, and the individual with its fibres all myelinated would be upset because the baby was constipated. So how would you deal with this situation involving the well-trained, myelinated, scientific grown-up, and the non-myelinated, unscientific little animal which has just turned up?

I think we ought to consider whether what I have been talking about is worth discussing. What difference does it make if the patient had these pre-natal experiences? What does it matter if the patient has come as a grown, mature human being into the office and shows signs which we might be inclined to believe are terror and dread of a kind that could be described as 'sub-thalamic' fear? – in terms of the Grid, beta- and alpha-elements, physical facts. Is it any business of ours as psychoanalysts? Is there any point in being sensitive to facts which are indistinguishable from imaginative conjectures? If the patient is able to have anxiety which he expresses by saying, "Doctor, I am afraid I am going mad", and we think that something is breaking in, interfering and interrupting his process of ordinary articulate verbal thinking, can we say anything to that same articulate individual which would seep back through the same route by which it floated up, and express itself in articulate and apparently rational ideas?

Referring to the fable we have just heard: Which animal should we talk to? And what language do we talk? What language do you talk if your dog chases a cat up a tree? Do you talk Portuguese? Or French? Or English? And why do you think that animal understands? Why do you think the animal will stop chasing the cat up the tree? Could

we talk to this patient in some language which would be understood at the address to which we would want it to go? If this is something primitive such as in a state of panic fear – remembering again the god Pan, and the adrenals, and the autonomic and sympathetic telephonic communications – what language do we talk which would be understood by the adrenals and make them stop running away from the enemy or madly against him?

There are certain areas such as the caudate nucleus, the optic chiasmas, where the wires seem to cross. So perhaps if we can talk to the area which has the cerebral hemispheres at its disposal and information made available by the sympathetic and para-sympathetic fibres, the communication could travel in both directions – to the 'cerebral spheres' and to the 'origin'.

2

Bion: I continue where we left off, considering the problem of giving the patient an interpretation which is addressed to a particular aspect of his statement. We listen to the statement, but we also observe what we consider to be the personality. I don't know how we could satisfy a scientist who asked, "What is a personality?" It is not very satisfactory to look up the word in a dictionary.

I recall a patient who talked freely and easily; he said that he didn't have dreams and that he had no imagination. For month after month he came to every session, never failed, never had an illness, never caught cold. When he got onto the couch he seemed to have some difficulty about which I did not bother much because it appeared to be simply a question of adjusting his clothes and his comfort. But after about three months I began to think this was very peculiar.

He always lay in a slightly awkward position on the couch; he would lie flat and then raise his head as if he were struggling against some sort of opposition and trying to see his feet. He did that three or four times. I had no idea what he was doing or even how to tell myself what this peculiar movement was. He was so co-operative, so rational, and I was kept very well informed. He said that he only slept an hour or two each night and worked for about sixteen hours a day, seven days a week. There were no complaints when I took a break or at week-ends; no disturbance, no depression, whereas with other patients I am used to some kind of reaction to the fact that I am stopping.

I thought I would change my vertex because I could not see anything very much from where I was observing the patient. When I did that, it occurred to me that his precise and exact position on the couch could be comprehensible if he were lying on the edge of a precipice.

And then his posture began to look like a cataleptic attitude. Indeed, the whole analysis began to look like a compulsive ritual – the same hour, the same behaviour, no diversion from that position at all. The more I saw of him the more I thought that these were not ordinary communications and that my interpretations themselves fitted into the pattern. I wondered what kind of psychiatric diagnosis I could make. The nearest I could get to one was that the total situation in the consulting room was a *folie à deux*, and that I was just playing a part in this relationship. Then I began to look at and listen to the behaviour of both these people, one of whom was myself. I continued to observe and listen to that peculiar conversation. The 'free associations' and the interpretations fitted in beautifully. You could call it the marriage of two minds – but there was something wrong with it. You could not call it homosexual; you could not call it heterosexual. In fact you could not call it sexual at all – not if the word 'sex' means the kind of thing that it means in botany, or physiology, or what I call psychoanalysis.

I managed to effect some change, because as the pattern became clear to me I felt I could also make it clear to the patient. I found a number of formulations which made it comprehensible to the patient that I had parted from him. Then it appeared that this same relationship existed between him and somebody else. I interpreted that the deficiency had been made good by his being able to enlist the co-operation of some other member of the public with which he had social relationships. After some time a change occurred again; now he fell back into having the same sort of relationship with himself – so I interpreted that. But I wondered what this 'Self' was. What does it mean – him Self, her Self, my Self? I found it unsatisfactory to talk about his 'body' and his 'mind' because both those words have a large aura of meaning. The body is a thing that you take to your physician; the mind you don't bother with. Indeed, if one talked about his 'mind' it was like talking about some unsupportable fiction, like talking about God to an atheist. The patient listened to the noise I was making, but it was devoid of content.

I tried giving it a location; I talked about his 'feelings', and the sort of thing he did 'up here', in his head. It was clear that he did not understand what I meant – or thought it was just nonsense anyway. He didn't say that; he was polite – he simply ignored any

reference to 'up here' or 'down there'. So I fell back on still talking about his 'Self'. I said, "Now you are talking as if your Self was located in your spleen". Sometimes I could have said that it was located in his adrenals, but I didn't have to because he talked about people who 'ran away', or people who were 'very aggressive'. I was able to say, "This person who you say runs away, and this person you say is very aggressive, are the same person. I think they are your Self". This peculiar mobility became more and more pronounced; I had to go on chasing this Self around what seemed to be various anatomical areas.

It became evident that the Self was not within the limits of what I call the body. I had to extend my interpretations over an area which had different boundaries – indeed it had *no* boundaries. In order to express it at all I would have to borrow a term like 'infinity'. It reminded me of Milton's words which express it so well: "Won from the void and formless infinite". He speaks about being "long detained in that obscure sojourn"; about outer and inner darkness, middle darkness and "up to re-ascend though hard and rare". That is a good description of this patient, as if he had descended into what psychoanalysts call 'the unconscious' and remained there a long time – "though long detained in that obscure sojourn", "and up to re-ascend". But when he does re-ascend, instead of emerging into the realms of light, he finds himself blinded.

Melanie Klein gave me an interpretation which puzzled me for a long time. She said, "You feel mutilated, castrated, as you emerge from the womb". That sounded like pure nonsense to me. By that time I was also seeing a patient, so I thought I would try it out on him too. Between us there seemed to be some truth in it; it did seem as if getting born was a dangerous experience in which the mother, or the mother's genitalia mutilated the baby. Further experience over the years had made me feel that this is also true in the many re-births which could be said to take place between the time when we are born – in the obstetrical sense – and the time when we die. This includes the time when we emerge from one state of mind into another.

What about waking up? The state of mind in which we are now is one in which we have our senses – in the neurological sense – active. But we do not know what we do, and what we see, and where we go when we are in the state of mind in which we are when we are

asleep. People talk readily about having "had a dream last night"; it is difficult to point out to them that one would like to ask, "How did you know it was a dream?" The patient I have been talking about was quite right – he didn't dream. When, according to most of us, he was in bed and asleep he went to places and he saw things just as much as he did when he was awake. But dream? No. That is the sort of thing that is done by people who have dreams, who go to bed and go to sleep; but not to people like my patient. People like that don't get ill; they don't have dreams. However, such a person is also extremely intelligent; so he learns the kind of language that I talk and says, "I had a dream last night", and then tells me a story which I think sounds like a perfectly ordinary fact. When he said he had a dream, met so-and-so and was very annoyed with him, he had in fact done so. I knew because I heard the story from that same person of whom he had 'dreamed' who also came to me for analysis.

What language ought I to have talked to this patient? And what should I have said to him if I knew that language? It is clear that the language he was talking was extremely accurate; I could rely on his statements as easily as I could rely on his coming to the consulting room with such accuracy that I could correct my watch by the time of his arrival. There was no question of his being late – my watch might be fast or slow, but not he. I don't know what clock he was going by, but he was right. So in fact I cannot tell you anything about how to analyse that patient, but I hope you will be able to tell me something.

Q: What is the relationship between memory and intuition on the one hand, and your concept of thoughts without a thinker on the other?

B: To take the last point first: Let us imagine that when a number of people collect together like this, there are stray thoughts floating around trying to find a mind to settle in. Can we as individuals catch one of these wild thoughts without being too particular about what race or category it is, whether it is a memory or an intuition, and however strange or however savage or friendly it might be, give it a home and then allow it to escape from your mouth – in other words, give it birth. To put it in other terms, can we catch a germ of an idea and plant it where it can begin to develop until it is mature enough for it to be born? We do not have immediately to expel the wild thought or the germ of an idea until we think it would be viable if it were made public. When we make it public, then we can have a look at it and

decide whether to call it a memory, or an intuition, or a prediction, a prophetic statement, or even a diseased germ.[1]

If you were analysing a child you could say, "I see you have brought your baby" – it might be a doll or a piece of cloth. If the child says, "I haven't got a baby; I couldn't have a baby", then you might say, "Perhaps it hasn't been born yet". That would be the germ of an idea, or the germ of an unborn child, the child that hasn't happened yet.

Parents say, "Why can't you children play properly? what are you quarrelling and fighting about all the time?" But the children don't know what they are fighting about; they would have to be prophets to know. Similarly with the thought without a thinker, the thought which is looking for somebody in whom 'it could be thought about'; or, from the point of view of us as individuals, the wild thought which is in the air but which nobody has dared to think so far because we are afraid of being asked, "Why are you playing with that dirty idea? Why do you play with these nasty thoughts? You ought to be good – a nice girl, a nice boy, a nice psychoanalyst". It is difficult to stick to one's right to be a nasty psychoanalyst who has nasty thoughts and who is willing to give a home to still more nasty thoughts. I suggest that you do that with one of these wild thoughts whether it be called dirty, nasty, psychotic, banal or ordinary.

There is no shortage of abusive terms for the idea. You might even, in spite of everything, call it 'Narcissus'. It could admire itself in a mirror or pool of water. But "*Fluctuat nec murgitur*" – don't let the nice little Narcissus fall into the pool in which it is admiring its features, and get drowned. When you have one of these wild thoughts, or one of these germs of a wild idea, you need to have the courage to protect it from people who want to dispose of it or send it to a psychiatric hospital – for the best of reasons, of course. It is much better to shut up Solzhenitsyn where he would be properly looked after and cared for instead of running about wild. So, whether your child is called Narcissus or whether it is called Solzhenitsyn, you need to be able to look after it – or somebody else will look after it for you.

Has anybody else any wild thoughts?

---

[1]It would be easier to detect and to think about the germ of a disease. I think the analyst has to exercise discrimination with regard to ideas that come to his mind.

Q: Using your illustration of the two fighting armies (who do not reveal anything known and therefore keep up the tension of the unknown) as a model of the psychoanalytic work, to what extent can psychoanalysis cause the 'disease', just as soldiers may become mad in war?

B: There is always a chance that the opposed armies, on the strength of the shared emotion of terror, will fraternize. As for the individual, I remember one of my men, a young fellow of about nineteen, who began to smile in an extremely irritating manner. The senior N.C.O. wanted to have him punished for a crime which was called 'dumb insolence'. That smile was peculiarly irritating in the sense that neurologists talk about the nerve which is irritated and also in the sense in which socially we talk about being annoyed. The question was, who had gone mad? Who was in-sane? Un-healthy? We, who kept on fighting? Or this boy who had had a psychotic breakdown? Was it a burst of common sense which had broken out in him, while the rest of us when on with our shared psychosis, our continuous, murderous marriage with the enemy? Lots of people were frightened of breaking out; in the air force crews were afraid that they only had to go on flying combatant missions long enough and they would get killed. It is dangerous enough flying around anyway; it is insane to fly about when people are firing guns at you. What were these fighting pilots afraid of? Becoming ill? Or becoming sane? So far we seem capable of having a mass psychosis in which we all agree to go about in disciplined and organized gangs of murderers, dedicated to the destruction of people who wear different clothes. Sometimes we don't even bother with the uniform if we can say, "I am black; he is white; therefore he is wrong". Or, "I am white and he is black and therefore he is wrong". The colour of the skin saves us the trouble of going inside that skin. And yet *we* are addicted to respecting the individual; we treat individuals as if they mattered. And in many ways we behave as if it is a good thing to help an individual to be one who has thoughts and ideas of his own. Unfortunately our dedication to that ideal seems to be slender; while we are dedicated to the rights of an individual to have thoughts or ideas of his own, before we know what has happened we have become 'Kleinians' or –

Interpreter: – I would like to know what 'Kleinian' means.

B: You are optimistic. Even Mrs Klein didn't know what it meant – she protested at being called a 'Kleinian'. But, as Betty Joseph told

her, "You are too late – you are Kleinian whether you like it or not". There was nothing she could do about it. So – although we aspire to respect the individual, bigotry rears its ugly head again. While I have the aspiration to respect individuals it does not surprise me at all to find that I am bigoted about something else.

Q: Why do certain patients try to keep things the way they are – they don't want to get cured, have no faith in getting better, prefer illness. What is it that makes them avoid getting better?

B: It depends who says it is, "better". As I have said before, when a quadruped got onto its hind legs and walked on two feet instead of four it started trouble. Not only does it have to be a very capable athlete to be able to balance on two feet instead of four; imagine the difficulty when our nervous system developed cerebral spheres, when our body, which was a happy dinosaur, suddenly started turning into a mammal and then the poor mammal started growing a mind. That is where we are now. We seem to have minds; then our minds have brain children which are a nuisance. So it is not surprising that we hate thinking and anything that makes us think.

It is clear that we should think properly, but where do we do our thinking? Up in our heads? Or down on our two feet that have to walk around? Or in our genitalia? Or our diaphragm? Or some part of our hypochondria? We don't like hypochondriacs; but suppose we have to do our thinking with the co-operation of our hypochondria. Sometimes it seems as if we have to do our thinking with something which is very thin, like a diaphragm. Being balanced on the knife edge of a diaphragm is even more difficult than lying on the thin edge of a precipice – or even a couch. You are liable to fall onto the floor – or to fall on the other side and be quite comfortable. Some people prefer the knife edge – they are frightened of being well off, they are frightened of being comfortable. We might say, "And down to descend to that obscure sojourn and be long detained there in middle and outer darkness".

This is the problem: Thinking is a development which is very unwelcome; unwelcome because it might make us more comfortable; unwelcome because it might make us more uncomfortable. It is difficult to know what to do with the capacity to think.

3

Bion: Before I start airing some more views perhaps you would like to raise any topics which you think need to have further exploration.

Q: How can an observer say that another person is thinking thoughts or not thinking thoughts?

Q: You described how you changed your vertex the better to understand what was happening with a patient. I would like you to talk more about this.

Q: The object of life is to get closer to the truth. How far would you consider madness the only way to get closer to reality?

Q: I would like you to say more about rational conjectures and imaginative conjectures.

Q: I would like you to speak about the specific communication within an analysis. Also, the difference between psychoanalytic conversation and other kinds of talk.

B: First, I will try to approach this profound question of getting to know the truth. To take a simple example: An infant sees something that it wants and discovers that it is out of reach. So it starts to crawl towards it. In this way it is reacting in a complex fashion. It is difficult to say of what it is thinking because the infant may not have learnt how to use its own methods of communication. As far as crawling to the object is concerned it discovers that it is very hard work. I don't know how it learns to use its 'voluntary musculature' as we call it; it is already a complex activity. It involves the use of the eyes; it involves the activation of an ambition to reach whatever it is that is out of reach. To answer the question – How do we know the infant is thinking thoughts? – we have to resort to imaginative conjecture. We cannot ask the child, and there is no way of thinking about what it is thinking about. But if the baby starts crawling towards the fire

because the flames look so pretty, then the imaginative conjecture can become a rational conjecture – you still don't know what it is trying to do, but you can think it may be going to take hold of a pretty piece of fire. So the observer – the mother, father or nurse – begins to feel a certain degree of alarm and gets ready to stop the child from putting its hand on the coals of fire. As the child makes further elements of an approach towards the fire the observer translates his rational conjectures into something like probabilities and prepares to make muscular movements to get between the baby and the fire. In the meantime the baby may have become tired, cannot be supported by its four limbs and bumps its head. So the ground hurts it. I don't know how it is done, but the baby resorts to its vocal chords and lets out a yell. What is the interpretation of that yell? It seems to be as undifferentiated as, say, a motor horn. When you are walking, or driving in a car, you have to translate that motor horn; you have to decide what the address is to which it is being directed and then make up your mind whether you will do anything about it or not. Getting back to the baby, I don't think the mother would have to go through a long and obscure series of thoughts; if she were capable of being concerned for the child she would pick it up and soothe it because it was hurt. It will be a black day for babies if mothers have to have a psychoanalysis before they can pick up their babies and kiss them. Perhaps we shall come to that one of these days, but in the meantime I hope we shall be wild and natural enough to go straight to the point.

A lot can happen between the time when the baby is learning to crawl and the time when the baby is driving a motor car and listening to, or interpreting, or sounding its horn. This raises another series of questions: How old is the baby when it learns to cry? How old is the grown-up who is driving the car? It is an important question because the ability to drive a car is a technical accomplishment; it is more easily achieved and can develop faster than its wisdom. Conversely, a baby could be wiser than a grown-up, especially a grown-up who is so technically equipped that he would have to go through all these analytic processes before deciding to intervene between the baby and the fire. But are the tests adequate to answer the problem of whether a person is wise enough to be allowed to drive a car? Tragic accidents occur because a child is athletically able to ride a bicycle; it can do so as soon as it gets a chance of escaping from parental prohibitions. But the child hasn't enough wisdom to know that that little bicycle ride

may change its life completely, either because it gets knocked down and badly injured, or, more tragically, it is killed. How is the parent to make available to the child that degree of wisdom he or she has acquired?

Q: This is a story, used as an analogy, of an expedition to the Amazon jungle in which a group of people got lost. One of them was so frightened that he shot a mortar into some trees. Consequently enormous pieces of wood came clattering down and killed some of the group. Nevertheless this accident also opened up a hole in the dense vegetation so that it was possible to use it to send up a smoke signal for help. The analogy I want to make is with the opening up of new ways through a careless act of destruction; and with the risk of using thinking to propagate non-thinking.

B: Nowadays not only the vegetable world but the animal world also is getting too crowded. To clear a space we could employ a very effective but somewhat indiscriminate method of clearance, one not much more discriminating than the baby's yell or the motorist's horn, but much more powerful – an atomic bomb; or a 'new and improved' atomic bomb, a neutron bomb. That would clear quite a space for other forms of life. In this way the human animal is now able to get rid of itself and make room for some improved form of life, maybe something which is impervious to what to us are lethal rays.[1]

B: Somebody has let loose a verbal bomb! So far it has only started us thinking which we hope is less lethal than the neutron bomb. So possibly the intervention of the delaying action of thought between the impulse and its immediate action may produce enough time for second thoughts. Otherwise first thoughts will be enough. In the Apocrypha – Ecclesiasticus – there is a saying, "Wisdom cometh to the learned man through opportunity for leisure". But the person has to be learned first and then has to have leisure enough to enable him to become wise. The problem is that learned men can produce and perfect a neutron bomb possibly faster than we can provide the leisure to think. It is so often a matter of acting first and repenting at leisure.

Q: I would like to suggest a model. A geologist went out with his dog in search of rocks. He tried to rid himself of the memory of

[1]There followed a discussion about the Portuguese translation of 'impervious'.

past things in order to grasp new knowledge. But he lost his way and became very hungry. He finally killed his dog and ate it. Afterwards, seeing the scattered bones on the ground, he started to lament, "What a pity my dog isn't here to eat all these bones." The moral is one of St. Augustine's sayings; "In order to cultivate the spirit and reason it is necessary first of all to cultivate one's bodily needs". This model refers to events that occur between a patient and his analyst; what is this catastrophic situation between the geologist and his dog in their expedition to explore the unknown?

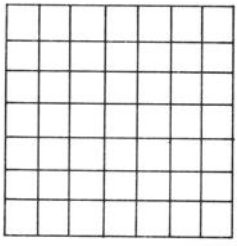
B: St. Augustine had good reason to know that the great Roman Empire had gone. The only things that were left were the bones of the martyrs. He proposed in the place of the destroyed Roman Empire to erect the City of God. Today we can have an idea of what point in this story we have reached. We can hear this imaginative conjecture – the fable – and compare it with where we have got to in that story. The fable could be said to have turned into history, and the history is a pageant in which we are now ourselves taking part.

I would like now to say more in answer to the question about the vertex. I borrow the word from mathematics, but there is a difficulty about borrowing these words to use them for a different purpose from that for which they were created. I do so not because I want to make things more difficult, but because the existing meaning of the word tends to create a difficulty when it is being used in a new way and in a new context. There is nothing new about that difficulty.

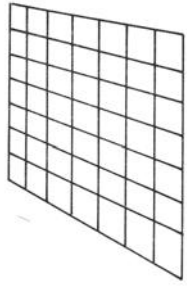
For example, Euclid elaborated geometry. It was useful and has lasted for over two thousand years. But Euclidean geometry runs into difficulties when it comes to the question of parallel lines. If you could walk between those two lines you might gradually come to the end, and by that time they would be wide apart. If you turned round and looked back to where you had come from you would find that the parallel lines had come together behind you. This is similar to what happens if you live long enough; the problems which have been solved become unsolved because you have changed; therefore all the relationships that you had have changed. The relationship between you and your home is different at the age of one from that at the age of two or three. I am not talking about A or B, but the *relationship between* A and B, the part in between, the umbilical cord, whatever takes the place of the umbilical cord, whatever it is that connects you with your parents and your parents' parents, and with all the other

objects with which you have a relationship. If Euclid could return today he might want to know what algebraic projective geometry is. He would have difficulty with it because there would be no lines or circles or other pictorial images. But can one say that algebraic geometry is superior to Euclidean geometry? There is no real conflict; algebraic geometry was *implicit* in Euclidean geometry, and what was implicit has now been made *explicit*. So Euclid might in time begin to recognize his brain children.

It might be helpful if we were sufficiently flexible to change our vertex so that we could look at ourselves. Cortez, according to Keats,[1] could stand, "silent upon a peak in Darien", with, "a wild surmise" – a wild thought – an imaginative conjecture, and see the world that he had discovered and what it looks like today – that is assuming that Cortez was sufficiently flexible. Can we do anything to keep our mental muscles in good working? For this purpose it would be useful to have a grid which we could mentally climb around. If we could turn the Grid then the distances between the lines would become very fine – the Grid can be turned into a Grating.



Grid



Grating

Putting it in another way: Newton's description of optics can be considered in terms of wave lengths; the distance between the climax of one wave and the next is quite large. But by changing your vertex you can make it much smaller; you can measure the distance between ultra-violet and infra-red with some very fine gradations, in terms of angstrom units. We use certain words, like 'love' and 'hate', in a crude way; each can be split into intermediate gradations. For example, the baby might love bright colours and food that tasted nice. Still in the 'love' category as it were, adult love can become passionate love, and the passionate love can become 'spiritual' love. As analysts we can

[1]John Keats, *On First Looking into Chapman's Homer*.

see all this in any relationship between the patient's Self and our Self. What about this bit in between? What about what we call an 'analogy'? In the analogy the two anchors don't matter very much, but the bit in between does matter. I think that is what Freud is driving at when he talks about the 'transference'; he means the bit in between the patient's Self and the analyst's Self.

The transference is transient, it is temporary; it is not the same at the end of a session as it is at the beginning. The beginning and the end of the session is a crude division. We need to be able to look at it through a Grating in which the divisions are not fifty-five minutes or ten minutes or ten seconds. When it is a question of drawing attention to the relationship between the analyst and the analysand we have to judge the *speed* of the change because some patients have a lot of difficulty in judging time and distance. A patient may come ten minutes late, wants to leave five minutes early, looks at his watch and says, "I must go – that was a very short session!" He is surprised; he doesn't know what has happened to that session – why is it so short? Or the patient doesn't bother about thinking which slows up things so much between the impulse and the action, has the impulse to leave and goes without thinking; it is much quicker. I have had the experience in which I was in Los Angeles and the patient wanted to come and see me, but he found he was in London because he went from Los Angeles to London without wasting time in thinking first – went straight from the impulse to the action.

We are concerned with having respect for thinking, how to think clearly and how to pass it on. We not only have to learn to think in such a way that we understand what we are thinking about, but we have to translate it into some form which our analysands or others will be able to understand. This is something that artists seem to be able to do; if we read of Shakespeare's case histories which we call a 'play' it still reminds us of real people. How many psychoanalytical papers remind of real people? Beethoven could write marks on a piece of paper which some people can translate into musical sounds that make us feel we know what he meant. Leonardo could 'draw a line round' what he saw so that *we* can still see what he thought a human being looked like; Giotto let us see what he thought God looked like. What form of artists can we be, and what work of art can we produce so that some of our offspring will be able to understand what we want to transmit?

4

Bion: We who occupy a certain position in the story of the development of the human culture can know a little about the history of where we have come from so far and, if we look back on our road, the route we have followed. But it is difficult to know what words to use when we want to talk about the 'road' or the 'route' which psychoanalysts are trying to follow. There are so many histories – of religion, mathematics, economics, civilization – but how would you write the history of psychoanalysis? Where would you start it? Which is the origin from which it springs? How have we got from there to here? It is hard to see – to fall back on a sort of psychoanalytically oriented genealogical history – who are our ancestors and what way our offspring are going. If we talk about genetic history we could suppose that the process followed Mendelian laws: A distinction was made between what were supposed to be the laws of inheritance, which followed Mendelian laws, and other things which were considered to be acquired characteristics, transmissible. But Mendelian laws don't help us much in considering the question of the inheritance of psychoanalytic development.

It is convenient to talk about the "British Psychoanalytical Society", the "French Psychoanalytic Society", the "Brazilian", and so on; at first sight it would appear that that probably followed Mendelian laws. But when we think that we are discussing the mind or the personality or the character, then it becomes difficult to say what laws that inheritance follows. We could say: who has inherited Freud's ideas? Obviously Mendelian inheritance would be useful – Freud's children and Freud's grandchildren. But suppose we think that people who had no blood relationship with Freud had something to do

with this story; how do they come to have psychoanalytic ideas? Who or what are these people, and where do they come in the story?

Last time I mentioned that Euclid might not be able to recognize the statements and formulations of algebraic projective geometry. If Freud came back today would be understand what we are talking about? Would he recognize what we say is psychoanalysis? Or would he say, "These aren't my children; these are bastards"? He might have to readjust his views about his progeny – all these theories and ideas which have sprouted up. In fact, the trouble started when Freud was still alive. He and Jung and Stekel got together and admitted that Freud was the only one who was entitled to consider that what he had said was psychoanalysis *was* psychoanalysis. It was agreed that Jung would call his school 'analytical psychology', and Stekel would call his 'individual psychology'. So they were split up; what had started as one became three. Now each of the three has split up into many more – poly-psychological. So we could say that we have lost track of the psychoanalytic line of inheritance. Yet we feel that we would like to say, "This is the Way; this is the Way from which we must not diverge too much. We should remain free to have our own ideas and opinions, but not too far from the Way."

The Way played a big part in the history of human civilization long before anybody had heard or thought of what Freud called psychoanalysis. A Chinese monk wrote about The Tao, The Way. Biologists think we have diverted, that we are a branch of the Simian inheritance. So even by making mistakes we are sometimes right.

I wonder if it is within the rules of psychoanalysis to be able to laugh at ourselves? Is it according to the rules of psychoanalysis that we should be amused and find things funny? Is it permissible to enjoy a psychoanalytic meeting? I suggest that, having broken through in this revolutionary matter of being amused in the sacred progress of psychoanalysis, we might as well continue to see where that more joyous state of mind might take us.

Q: These discussions have usually focussed or the catastrophic aspects of destructiveness. I would like to suggest another side – something lighter and happier. I submit some clinical material which I gathered during supervision of a case with an eight year old boy.

He begins a session by making a plasticine ball and then suggests a game of football between a boy and a girl. He soon leaves this game

and picks up a box of coloured pencils, empties it and brings it up to his eyes, giving the impression that he is looking at his analyst through binoculars. The analyst says that when he uses the box in that way he is able to see her even when she is far away, for example, when he looks at her at the club on Sundays. The boy asks her what time it is and puts the box on the table saying that it is a tunnel. He puts his hand through it and, picking up the plasticine ball and a doll, he adds, "this is a machine that changes things. When I put a doll inside it a girl comes out".

The analyst says, "It is like a mother into whom a father goes and a baby comes out". After hearing this interpretation the boy continues to play more enthusiastically with his 'tunnel of transformation' saying, "A cup goes in, a doll comes out; a doll goes in, a cup comes out". The analyst then repeats the interpretation she gave him before. I want to call attention to this 'tunnel of transformation' that this child uses with such enthusiasm and happiness during a session, discovering something new without the need of destructiveness. I have noticed that we refer to a fear of the disappearance of psychoanalysis. Does this fear lead us into a protective attitude towards psychoanalysis? Or does it cause us to leave psychoanalysis unprotected by an overprotectiveness, contributing unknowingly to its disappearance by suffocating it?

B: That is a striking example. I wonder if others are as impressed as I am, before I take up the train of thought it arouses in me.

Q. In Rio de Janeiro there are two Psychoanalytical Societies and two Group Societies. Analysts belonging to the Psychoanalytical Society usually also belong to the Group Society; the same people belonging to one society belong to the other. So that the problems that befall the Psychoanalytical Society are basically the same as those of the Group Society. For example, in both societies the subject concerning the admittance of non-medical students is discussed. The degree of passionate involvement in these discussions reaches an almost violent level when the discussion takes place in a psychoanalytic society meeting. When this same problem is discussed in the Group Society with the same people present, the same level of destructiveness is not reached. I repeat; the members are the same in one society as they are in the other.

B: One of the advantages of a group of people – for example, this meeting itself – is that you can often see something spread out

amongst all of us which in the individual psychoanalysis one sees in a more precise way. Freud himself seemed to be disconcerted when the first International Congress was held; he thought they could all get together. Instead of that it appeared that they all fell out with each other. So instead of leading to a union of views, it led to a great diversity of views.

The story of the Tower of Babel crops up again and again. It seems that when people unite to storm the citadel of the human mind they fall apart in a primitive way; they join in order to run away from something or to fight something. That seems to me to be a spread out example, as if the body politic were developing a kind of adrenal activity. In a physical human body one could say that the human embryo was beginning to bud off the adrenals which sooner or later would begin to produce adrenalin. But so does the human group; whatever scientific products they produce, they also seem to produce a great deal of adrenalin. So you can detect a primitive, emotional reaction. The individual human being, according to genetic theory, seems to be produced by the fusion of gametes which are derived both from the man and the woman. But since the individual has a father *and* a mother it is not surprising that it has characteristics which are both male and female.

Rio, I gather, has two societies; that when the people get together in one of them they behave in a somewhat masculine or aggressive manner; when the same people get together in another society they behave in a passive manner.

Are there male and female societies? They are composed of the same people, so it is no good asking the obstetricians. I think we would have to ask psychoanalysts – in fact, ourselves.

Now I want to draw attention to something which I constantly come across – psychoanalytic pessimism. Milton, when he was not yet twenty years old, protested against what he called being "sunk in an oedipean gloom". I sometimes think that analysts are sunk in this same oedipean gloom; so much so that they are often taken by surprise when they discover that there is such a thing as mental pain. One feels that they have only learnt that there is a *theory* that there is mental pain but that they don't believe it exists, or that psychoanalysis is a method of treating it. So when a patient gets 'better' they are surprised; they don't believe it has anything to do with the work they are doing. The clinical example about the child is important because

it is a reminder that patients do become happier and more able to be creative or constructive, and change from being primitively dominated by flight and fighting. After all, embryos develop; they don't only have adrenal glands. Other portions of the anatomy develop in the embryo itself, and life, with any luck, does not stop short at birth. The full-term foetus continues to grow after birth, so although it may start by running away from or fighting its brother or sister it also begins to grow out of that stage. The psychoanalytic procedure does a great deal to help that development to take place, just as much as the work of paediatricians helps to keep babies and children healthy so that they can go on developing. Psychoanalysis helps the spirit, or soul, or super-soul, or ego, or id, or superego – whatever name you want to give it – to continue. Plato describes in the *Theaetetus* how Socrates says that he is a kind of mental midwife. I don't see why we should not claim mental development, mental ancestors, one of them being Socrates himself. If that is so, we too could say we are a modern version of mental midwives; we help the soul or psyche to be born, and even help it to continue to develop *after* it is born. We should not consider ourselves to be simply historians of the past grandeurs of psychoanalysis. We are not dead yet and there is no necessity to spend our time attending our own funeral service. I don't find it interesting to be perpetually celebrating the obsequies of psychoanalysis; I like also to be attending one of its many re-births.

While we do not want to forget our famous men let us by all means praise famous men and women of our own time, our mothers as well as our fathers, because even our mothers had something to do with begetting us, so they might as well be given a passing reference sometimes. I hope that the masculine society in Rio will occasionally say "How do you do?" to the more passive society – even if they are the same people.

Q. I would like to present for your consideration the observations made by the physicist, Werner Heisenberg, and by a psychoanalyst, Luis Chiozza.

Heisenberg asserted that it is impossible to calculate the trajectory of an electron because there is no such trajectory and that in the description of these phenomena it is impossible to separate the observer from the rest of nature, impossible to make a scientific observation when the interaction between observer and observed is ignored. This he called The Uncertainty Principle.

Luis Chiozza, an Argentinian training analyst, basing himself on Freud's writings about the sexual theory, "Instincts and Their Vicissitudes" (1915c), concludes that every psychic process constitutes a somatic matrix for qualitatively differentiated impulses. At the same time these impulses are unconscious, particular fantasies which he calls "specific fantasy".

Curious contributions to human thought! On the one hand we have a physicist – who deals with objective, rational and precise mechanisms – describing an Uncertainty Principle; on the other hand a psychoanalyst – who deals with subjective, irrational and imprecise resources – describing the Specific Fantasy.

B: A lot of people attach importance to what we call the 'truth'. Some of them are painters; some musicians; others mathematicians; some are psychoanalysts. I don't know what Freud meant by 'scientific method', but it seems to me that the basic idea is to bring truth to bear. I am not surprised that we think that some people are important painters; there is something about their work which makes us feel that they are not trying to make fools of us all; they are trying to show us the truth. The same is true of some sculptors who make structures which trap the light, sometimes with a piece of projecting material, sometimes with a hole which goes right through. If we look at the light which has been trapped then we may be able to see the truth which the sculptor is trying to show us. Mathematicians formulate projective algebraic formulae; they are not trying to make life more difficult; they are talking the simplest, most precise language they know. If we take the trouble to listen to what they are saying then we might learn something.

Psychoanalysts think that what we are trying to observe is disturbed by who we are. Judges in the law courts, trying to find out who is guilty, have also discovered that there are difficulties about answering the simple question – guilty or not guilty? Heisenberg has stated clearly his Uncertainty Principle, but in his search for the truth he discovered not only the Uncertainty Principle but the possibility that there is such a thing as uncertainty. But uncertainty has no colour, no smell; it is not palpable, but it exists. And in the course of this journey which the human race makes in its attempt to reach the truth we discover that we observers disturb the thing we are observing.

Even the most advanced human thinkers are only at an embryonic stage. We have only just started thinking; we do not even know the

rules of thought; we do not know what to do with this newly acquired capacity for thinking.

Heisenberg's Uncertainty Principle is an important stage in the journey; it is deplorable that any section of mankind should be *certain*. If there is anything which is certain it is that certainty is wrong.

5

Bion: I have been explaining to the translator that I find it quite bad enough trying to translate what I want to say into English; I am therefore very thankful that I don't have to try to translate it into any other language. I would ask you to be indulgent to both of us. I don't think it is our fault – it is inherent in the difficulty of the matter I want to introduce.

For that reason I think that this subject will probably take at least four or five evenings to introduce. What I say will either seem to be incomprehensible, or so obvious that it is hardly worth saying. Whether it appears to be obscure or whether it appears to be obvious, in either case it will give you a misleading impression.

I will start by reminding you of what Melanie Klein says about projective identification and the depressive and paranoid-schizoid positions. The infant or very young child thinks it can split off nasty feelings and ideas, that is, anything which is unpleasant. According to her, the child has an *omnipotent phantasy* that it can split off these unpleasant thoughts or ideas and then evacuate them in the way that it can evacuate urine and faeces. She was referring to something she believed to be applicable *after birth*.

What I am going to say cannot aspire to the status of what is ordinarily called 'scientific thought'; the most that I can claim is that it is imaginative conjecture. The central point of this guess is that even before birth the foetus – I don't know how close to being a full-term foetus, or whether it could apply to the embryo from an early stage – becomes sensitive to what could be called 'happenings', events like the sense of the pulsation of its blood, physical pressure of a kind that can be communicated through a watery fluid such as amniotic fluid or even extra-cellular fluid. (When I refer to extracellular fluid I am

talking about a fluid which is as near as possible to something which is not polluted at all. The amniotic fluid is already polluted by meconium.) I can conceive of situations in which pressure is transmitted through the amniotic fluid and can therefore possibly stimulate the optic and auditory pits. Here I am guessing that even as embryo of three or four somites has something which will one day become what we call 'sensations'. I do not know what they are to be called – if they exist at all – in the intra-uterine period. Intra-uterine photography has shown the foetus with its arm raised as if to protect itself against a bright light. I don't know what that bright light would be unless it is the kind of light that one sees with changes of pressure on one's eyeball. The foetus can also be seen in these photographs sucking its thumb – indeed a child can actually be born with its thumb in its mouth. Both these bits of evidence seem to me to excuse rational conjectures. I certainly would not expect any scientific worker who is familiar with the discipline and the rigors of scientific thought to agree, but as psychoanalysts I think we have to fall back on such imaginative and rational conjectures. The whole of our subject could be attacked on the grounds that it is unscientific and cannot be supported by any scientific evidence. The most that could be claimed for it is that it is 'probable'.

I am supposing that the gametes of intelligent parents would be likely to fuse to produce what could be called an intelligent person I see no reason why a full-term foetus should not also be regarded as a potentially intelligent grown-up.

All of this is what I call a rational conjecture: I don't think it is possible to claim any more for it than that, otherwise it is distorting, devaluating the standards of scientific work. I can imagine that even the embryo could much dislike the feeling of blood pulsating through its system. Similarly, that it might dislike the effects of the early stages of production of adrenalin or other developing function. The more potentially sensitive or intelligent, the more it would be likely to be what could later be called 'aware of' these sensations, dislike them and therefore get rid of them. I think that what takes place at this stage is analogous to an omnipotent phantasy or scepticism; it is what will later be called a 'fact'. The foetus may take a wrong turning in development, become incapable of having 'feelings' or 'ideas' and so be born lacking important elements of its equipment. However, the post-natal creature still retains its potential for intelligent activity.

Amongst these activities which are retained is a capacity for imitation, mimesis, so that the 'intelligent' (as distinct from 'wise') baby or child is able to imitate fathers, mothers, brothers, sisters; it is 'well-adjusted'. Later, if the person is unfortunate enough to get into a court of law – as was the case with Loeb and Leopold – he could be judged according to what in England were known as the M'Naghten Rules: Does the accused know the difference between right and wrong? The kind of personality to which I am drawing attention – which could now be called by a psychiatrist a 'psychotic' – *does* know the difference between what is called right and wrong. Of course Loeb and Leopold knew that all these ordinary people call murder 'wrong'. So of course they knew that it was 'wrong' to commit what they called 'the perfect crime' and stuff the body of the murdered child into a drain – a scientific procedure which is not, by a sane person, called 'research'. So the barrister for the prosecution can justly argue that these people know the difference between right and wrong and are therefore guilty of the crime.

I mention this story to draw attention to the peculiar and frightening situation in which the very intelligent person is not capable of being wise. There are certain diseases in which there seems to be a defect in the domain of neurotransmitters. For a long time there were difficulties because there was something anomalous about the research findings. Although the administration of Leva Dopa seemed to have a curative effect on Parkinsonism, it was recently discovered that what is apparently a *lack* of dopamine is not so at all – the total amount of dopamine remains unaltered. Therefore it is puzzling to know why there appears to be a shortage. It now looks possible that the truth lies in the abnormal concentration of dopamine *receptors* in certain parts of the nervous system. We analysts are faced with a similar paradox. Why is a person, who is apparently highly intelligent, lacking in wisdom? You would think such a person would naturally go on to be wise as well. Consider your own analytic experience. Have you ever come across people who you feel must be extremely intelligent in order to be so stupid. It sounds like a clever paradox to say, "There is no fool like a stupid fool; and there is no stupid fool like an intelligent one".[1] Why is it that so many highly intelligent people

[1] "The wisest fool in Christendom" – remark attributed to Henry IV of France about James I of England.

seem to be incapable of being wise? What has happened to the intelligence? Is it, like trees that hide the wood, too thick to perceive the wisdom that lies beyond the cleverness?

Q: What could you tell us about Freud's formulation that an analyst should go back to analysis every five years? Can this be connected with intelligence or wisdom, or with pollution? – in its more modern sense, the great problem of mankind, what to do with our own garbage.

B: Let me repeat the quotation from Ecclesiasticus – "Wisdom cometh to the learned man through opportunity for leisure" (p. 332). A man or woman has to be capable of being learned and can then potentially be wise. We can learn a lot through the experience of having an analysis; when we stop we can also be said to have an opportunity for leisure. To come back to analysis might be an opportunity for clarifying the way to use knowledge. In that way we could become wiser and even have some opportunity for comparing what we thought we knew a few months or years back with what we know now. Have you tried reading some of the classics to which you were introduced when you were at school? They would appear to remain the same because they are there in print; but do the words, which are the same as the ones you studied at school, have any more meaning? I suggest the following: Be silent, and as quickly as possible write down what you can observe, either with all your senses about you – that is to say, with your eyes open – or with your eyes shut. Do the same thing again in half an hour, or two hours, or one day, or one week – whatever interval you like – then see if the lists are the same and if the order in which you have written these matters is the same or different. In that way you can compare what you were capable of observing some time ago with what you are capable of observing now. Could you say you were more, or less observant? Could you have any idea about whether you were wiser or not? If you had an idea that you were more observant, but had no idea whether you were wiser, then what is the difference between intelligent observation and wisdom? I am not saying, "Look it up in the dictionary", but I *am* saying, "Look it up in your mind".

Q: You have spoken of rational conjectures about the life of the foetus inside the womb. Would you tell us about one of your clinical experiences?

B: It is useful to me, as a model, if I am shown a photograph of a

foetus with its thumb in its mouth; or a foetus that raises its arm as if protecting its eyes. The same thing applies to these conjectures. I find foresight and prudence useful, but I am not a prophet, I am not a seer and I have to make do with rational conjectures. The insightful person or prophet or poet might be able to have much more convincing evidence for behaving with prudence or with foresight. But I have to fall back on these rational and imaginative conjectures. I don't think much of them, but they are the best I have.

Similarly in analysis: While I am trying to understand what the analysand is telling me, I have to guess, I have to conjecture until the patient can give me some more convincing evidence; then I may be able to feel reasonably sure of my interpretation.

Q: A writer said, "Life is a product of the conjunction of chemical reactions in intense and continuous movement". In reality we are never the same as we were in the immediately preceding moment. How do you see the temporal nature of the existential being, considering this process of continuous change?

B: Where do the maggots come from in a heap of dead and decaying stuff? How does this heap produce something which is alive and could be called a kind of animal? How would you define the difference between a chair, which seems to be made up of dead matter, and myself who am capable of walking about? What is your definition of the difference between 'dead' objects and 'live' ones? I have never seen any scientific definition of that. A dog would be uninterested in a photograph of another dog; it might smell it, but would show no further interest. But if I show a series of photographs on a screen that dog becomes excited and interested and may want to chase or fight the other dog. Why does it think that a photograph of a dog is uninteresting, but a series of photographs which give the illusion of movement is interesting? We are not in a much better position. In the investigation of life there are more and more elaborate descriptions of the DNA molecule, but we are no nearer, so far as I know, to life. I suggest that you should ask these questions again next time; I might have become wiser by then. At present I cannot answer them. I don't think there is anything wrong with the questions, but there is a great deal wrong with the answers.

Q: I would like to change the vertex and tell you a story about a psychoanalyst who died and went to Heaven. When he got there he met Saint Peter and showed him his Curriculum Vitae. Saint Peter

said he didn't like it. The analyst argued that he had been a good analyst, that he had treated neurotics and psychotics, written books and delivered lectures. Saint Peter said, "You were only looking for promotions and a way to gain access to power. There is no charity or humanity in that. Your fees, too, were quite high". Saint Peter then asked him if he could remember if he had at any time been charitable towards someone. The analyst thought and thought and finally remembered having done a charitable deed. "Oh. I once gave $20.00 to the poor!" Saint Peter then called his assistant Joshua and said, "Give this man $20.00 and show him the way to Hell". The moral of this fable is, "Love is paid with love; money is paid with money". Where, among us psychoanalysts and psychotherapists, does our humanity lie?

B: I don't know. I am afraid that if by some accident – which I think is very unlikely – I got sent to Heaven, there would be masses and masses of sheep, steers, birds, birds that never hatched out of their eggs, all giving evidence that they had been eaten by me. "Dr Bion, you are at the wrong address. Go back to Hell and get eaten yourself". I do not look forward to an eternity of bliss; enough is enough. In the words of a popular song, "It's love that makes the world go round". A realist looks for sources of energy.

6

Bion: In most scientific disciplines there are material objects to observe, but in the kind of work that we do the problems of observation are different. Even the word 'observation' has to be used by us in a peculiar manner because there is nothing to 'observe' in the way that we observe physical objects. Heisenberg's introduction of the Uncertainty Principle made it clear that even the observation of physical objects is not so simple as it may appear; those difficulties are inescapable when we observe what we call the 'mind'. Nevertheless, we have to observe before we theorize.

Francis Bacon described the possibility of approaching scientific work from above as if one was considering the general principle first and then arguing the existence of supporting evidence. The alternative is to observe the material evidence and then to deduce the general principle from the totality of the observations made. That, he said, is the correct approach. When we have to observe something which has no shape, smell, colour or sound, the problem of evidence – the counterpart of evidence of physical objects – is acute. And yet I do not think it is possible to be engaged on analytic work for long without being convinced that there is a mind. You can observe an animal which is not verbally articulate and yet be convinced that it is thinking. The same thing applies to very young children or even a newly born baby. I was asked yesterday what the clinical evidence was. There cannot be clinical evidence because nobody has analysed a foetus. But it is ridiculous to suppose that a new-born baby has no mind, or that a child of five has a mind but had no mind before infancy or before birth.

In carrying out an analytic investigation we should be aware of the fact that what Melanie Klein described as 'projective identification'

takes place even before birth – that is supposing that an embryo can be aware of primordial sensations. If we all became as silent as possible and then noted what we heard in the perfectly silent group, that would give some idea of what the embryo might be aware of. Here again, I have to borrow words from one state of mind and apply them to events in an entirely different state of mind. I find it difficult not to believe in Freud's theory of dreams, but the person who is awake and conscious knows what he saw or heard or experienced in a different state of mind, the state of mind when he was asleep. The person who is awake will believe that he is speaking the truth when he says he had a dream last night. How does he know he had a dream last night? The statement is made by a person who is wide awake; it is a theory of a person who is wide awake about a person who is in the state of mind that he is in when he is asleep.

When we observe a physically mature person is there any evidence of a survival of a different state of mind? Embryologists tell us that there are signs of the survival in the child or grown-up of a branchial cleft. But mature beings don't have branchial clefts; fishes do. A surgeon will say that there is a tumour in the coccyx, the vestigial tail. If that is so, is it not possible that in what we call the 'mind' there are also survivals? And that in certain states of mind these survivals could become apparent if we look in the right 'place'?

I suggest that when we are observing a physically mature person, in no way physically defective, it is possible to be sensitive to behaviour which is somehow peculiar, which does not fit in with what we would consider to be a healthy, normal mind.

I think there is a certain confusion in Freud's ideas of conscious and unconscious. Sometimes he talks about something that is conscious or unconscious; sometimes about a thing that is *in the* conscious – and that is a different idea. The situation I am discussing is one in which the idea of conscious and unconscious is not very illuminating; even the idea of *the* unconscious would be easier to discuss if one thought of it as a thing or place into which you could put something. If, as I suggested before, the embryo tries to rid itself of unpleasant or unwelcome primordial sensations, it could have 'ideas' or 'feelings' that had *never at any time been conscious*. The nearest I can get to describing it is that these 'ideas' or 'feelings' were 'available' or 'not available'; they have become out of reach of their origin. So when you are dealing with a grown person you will have to distinguish

between something that is conscious or unconscious, and something that is *inaccessible*.

What about these dreams? When the patient says he had a dream last night, why does he say so? If he is correct, then the theories of accepted classical psychoanalysis are applicable. However, suppose the patient says that he has no imagination, no dreams. What about that? We may have to consider the possibility that his dreams, his imaginations are not accessible or that he is communicating 'facts'. The patient may take up some athletic activity like wrestling, dancing, gymnastics, eurythmics. But the athletic activity can be a survival of primitive elements of the mind. To fall back on anatomical descriptions, one could say it is a function of the limbic nuclei or other aspects of the basal nuclei. Behaviour which appears to be irrational, or neurotic or hypochondriac is much more comprehensible if we think of it as a state in which the unconscious is where the conscious ought to be. Similarly behaviour called 'neurotic' or 'psychotic' can be based on 'facts' unobserved by us. Segal described a patient who talked about a violinist, saying that any fool could see that he was masturbating. The rest of us would think he was playing the violin – not so that patient.

The behaviour of certain patients – a smile for instance – is misleadingly similar to that of neurotics, hypochondriacs, or even a baby who is thought to be smiling because it has 'wind'. The expression on the faces of a piece of Etruscan funeral sculpture is sometimes called an 'archaic smile'; it appears to mean the same as a smile on any ordinary countenance, but it is not. I have known a man treated as a criminal for what in the army was called 'dumb insolence'; it is a mistaken interpretation. A psychiatrist would call it a symptom of schizophrenia, but I am not sure that that interpretation is good enough as far as psychoanalysts are concerned. We have to observe what the patient says to us, the flow of blood in his cheeks, or the lack of blood in his cheeks, or the movement of his muscles. Sometimes we can see peculiar movements in the voluntary musculature; sometimes there can be movement of involuntary muscle.

Although these movements of involuntary muscle can be betrayed on the X-ray screen if the patient has a barium meal, this kind of apparatus is not available in a psychoanalytic consultation; we have to learn a new way to observe.

Q: What are the causes of the inhibition of adequate thinking? Laziness? Search for ease? Or emotion?

B: There can be all those causes, but I am not sure that it is illuminating to consider the obstacles alone. However you want to express something in yourself – as a composer of music, or as a sculptor or a writer – all these approaches are difficult, partly because so many of the earliest years are spent in trying to get rid of who you are. As you say, there is an inhibition, an obstruction. A child tries to be good, tries to be who or what he thinks his father or mother wants him to be; a great deal of time is spent in trying to be *not* himself or herself. It is therefore hard to change to wanting to express who you are; it is like changing the direction of your thought. A sculptor can try to tell people, who are not him or her self, something they have not noticed hitherto by making a trap for light. Having made such a trap there has to be somebody who wants to look at it, but that person is more used to looking at the piece of stone than at the shape of the light. Similarly, a painter can depict something with his pigments on canvas; those pigments and that flat surface can trap light. So you can see a portrait painted by Picasso and fail to see what is drawn or painted on the canvas. You can say, "It doesn't look like any human face that I see". Nor does a sculpture by Rodin look like a statue such as the David by Michelangelo, or the Hermes portrayed by Praxiteles; they were portraying something in a different way. A writer may use words in a way which is not the same as the as the way in which they have so far been used. James Joyce said you ought to spend your life in reading *Finnegan's Wake*, and then you might understand what he means. The shape which is expressed by his words is different from the shape which is expressed by the words of, say, Shakespeare or Milton: artists have a way of expressing themselves which changes painting or sculpture or writing into something new.

Perhaps Shakespeare himself couldn't understand one of his own plays performed today. Or if Freud were able to come back he wouldn't understand psychoanalysis. These people do something to the human mind which means that it is never the same again. So the question is not so much what the inhibitions are, but what the person wants to pass on. What he does *not* want to pass on, what he wants to *in*hibit, is only a part of what he is trying to exhibit.

Q: I would like you to explain how you perceive the so-called psychosomatic illnesses.

B: I don't think that my explanation matters. What I would draw attention to is the *nature* of the problem. For example:

This (the palm of the hand) is a representation of the psychosomatic illness. Now watch: This (the back of the hand) is the soma-psychotic illness. It is the same hand; it is the same complaint. Looked at from one side it is psychosomatic; come round to the other side and you will see the soma-psychotic. Putting it into other words, if you don't feel satisfied at seeing a psychosomatic illness, change your vertex and look at it from the other side. The same thing with the inhibition: Look at it from one side and it says "No"; look at it from the other side and it says "Yes".

Q: I would like you to clarify certain attacks made by the patient on the analyst by the use of strong suicidal emotions.

B: The patient may be capable of arousing powerful feelings in the analyst. He can make me afraid that he will commit suicide; or he can make me feel love or hate. My ability to think clearly can easily be destroyed by a patient who plays on my emotions. While the analyst can say things which play on the patient, the patient can equally play on the analyst.

The problem for the analyst, or any other doctor, is how to help somebody who can stop him from thinking clearly. He can try to make it easier for the patient to think clearly; but the patient may not want to make it easier for the analyst to think clearly. A terrorist can terrify two people who want to discuss a problem – so the terrorist wins. The minimum conditions for discussion are destroyed because terror is not a state of mind which is conducive to clear thinking. The terrorist is able to mobilize fundamental and powerful feelings, feelings which are often expressed in a sophisticated manner as fighting or running away. But neither the activity of fighting nor the activity of running away is easily harmonized with thinking clearly. Terrorism is the weapon, the prerogative of the mentally deficient.

7

Bion: I have suggested that the potentially intelligent foetus resorts to a mechanism analogous to what Melanie Klein describes postnatally as 'projective identification'. These primordial germs of thought and feeling become inaccessible – that is to say, out of reach and control of what will later be the character or personality. That state of mind, as soon as the embryo or foetus can be said to have a mind, is different from that of the infant who displays thought and behaviour to which these concepts of conscious and unconscious are applicable. The infant or child who shows unconscious mechanisms and who behaves as if it had an unconscious does seem to experience some kind of caesura, which Rank called the 'birth trauma'. In other words, there is a continuity between the full-term foetus and the infant although the continuity is both maintained and broken by what appears to be a synapse, or diaphragm, or screen, so that the primordial thought of the foetus is projected onto this caesura and is reflected back from the infant to its primordial levels of thought and feeling. There is a contact through this permeable membrane in both directions; the caesura is a transparent mirror. The infant or child can experience feelings which seep up from the unconscious and which can similarly be affected in the opposite direction. That is to say, the thought of the infant or child can affect these primitive levels of behaviour. This is different from the state of affairs which exists in the embryonic growth of what we would later expect to be its mind. The separation of these two powers of thought is much more nearly complete, but a puzzling situation is produced because it does not *appear* to be like that. This same genetically gifted creature is able to start, *as if after birth*, to learn how to behave exactly like everybody else. At first one would suppose

that this organism is highly intelligent, can learn easily and is able to compete successfully with its brothers and sisters. It is therefore something of a surprise when at one of the periods of emotional turmoil such as adolescence, or latency which is another period of turbulence marked by apparent calm, peculiar kinds of behaviour start appearing. The child suddenly seems to be incapable of understanding or behaving in a common sense way; he behaves as if he had no common sense at all.

Conversely, when one expects bizarre behaviour he behaves in a logical way. I mentioned an example of this when I quoted the case of the patient who said that anybody knows that the violinist is masturbating in public.[1] In analysis it would be a long time before you were able to show a musician, or a patient who could play the violin, that he was using statements about playing the violin as a method of expressing unconscious, masturbatory desires. Thus, on the one hand there is the neurotic to whom it is difficult to demonstrate the existence of unconscious impulses, masturbatory activities and so on; on the other hand, the intelligent person who seems to be unable to appreciate beautiful violin playing, but has no difficulty whatsoever in seeing that the violinist is masturbating.

I think that there is some connection between this latter kind of personality – whom I will call, for convenience, 'psychotic' – and the one that I call 'neurotic'; between the psychotic mental activity and rational or socially acceptable behaviour. It seems to be accepted that the neurotic's ordinary, social, commonsense thinking has a psychotic base. This is what I think Melanie Klein means when she refers to the depressive position and the paranoid schizoid position; she is referring to levels of thinking and feeling which in isolation would be called 'psychotic'. She argues that the neurotic individual cannot be considered to be analysed until these psychotic elements have been displayed.

It is convenient to consider the psychotic patient as also being divisible, as being an 'insane' psychotic in contrast with a 'sane' psychotic. I am using the terms 'sane' and 'insane' with an emphasis on the Latin origins – 'healthy' and 'unhealthy'. The sane psychotic has vestiges of rational, conscious behaviour; something can be done to develop them.

---

[1]See reference to Hanna Segal in Talk 6.

The insane psychotic, on the other hand, finds his way into a psychiatric hospital and usually deteriorates there. What are you dealing with when somebody comes to your consulting room and wants an analysis? Is there any way in which you could formulate to yourself what category of person you think you are dealing with? It is not only an academic point because on the answer to that question depends whether you want to see the patient or not. That is something you have to decide almost at once. Indeed, one can say that you have to decide in haste and repent at leisure.

You may get a clue if you consider the caesura as a mental diaphragm. When you see your patient, how easily can you mentally change your position, your vertex, so that you can almost see both sides? If you feel disposed to analyse an asthmatic patient you will very soon find yourself in the kind of trouble that I can describe from an actual experience.

The patient is admitted to a medical ward as a case of asthma. The analyst sees the patient there, possibly in a ward with screens drawn round the bed, or possibly in a small sub-ward in which the analyst and patient are alone together. Within two or three sessions the patient's asthma gets worse. So far so good; nobody minds that because they think that asthmatic patients tend to have these relapses. But further progress in the analysis releases the patient's capacity for mobilizing the opinion of the ward. And the analyst finds his appearance is the signal for marked disapproval from all the inhabitants of the ward. It becomes clear that their sympathies are in support of the poor patient who is being so foolishly and unkindly talked to by the analyst. The patient, who may have been regarded as a bit of a nuisance, is now more generally regarded as a person of charm and intelligence. There is only one real defect – his addiction to psychoanalysis.

People cannot understand why such a nice man, such a gifted man, has that peculiar habit of going to see an analyst. In the course of the analytic sessions the patient can let drop an increasing number of unpleasing comments. He says that while he is determined to go on with the analysis, so-and-so, who is a very intelligent women, cannot think why he is so foolish as to go to that horrible doctor who clearly has no qualifications and is a stupid, unscrupulous money-maker.

He talks more and more of his unfortunate experience of having

to put up with these hostile comments about his analyst whom he so much admires. Further progress in the analysis leads to a situation in which the patient who has never experienced frustration, who has never had any fears of insanity and who has never been physically ill, now begins to catch colds, now begins to be afraid that he is going mad, begins to be unpopular, even has the impulse – which he has never had before – to commit suicide.

The state I have just described is remarkably reminiscent of that in which these primordial ailments are inaccessible, have never been conscious, because they have been got rid of *at source*. At a much later age these things which have been inaccessible, which have never been unconscious, which have never been conscious, now become both. The fear of suicide ceases to be a fear; it comes much nearer to a reality, making the threat of suicide dangerous. The patient will resist discussion of the impulse to commit suicide; he will mention it, but does not want to talk any more about it, If the analyst persists then be becomes responsible for putting thoughts of suicide into the patient's mind.

I think it is a good thing, before you see such a patient, to arrange your room so that you could interpose between a sudden impulse of that kind and the action which he can take quickly and suddenly. There is no real intervening phase between the expressed impulse or fear and its translation into action. Thus the stage is set for instantaneous catastrophe. It is not much good hospitalizing such a patient; there is no alternative to going on with the analysis – or none that I know of. This patient has never had the experience – which most people have had – of being afraid of insanity, afraid of masturbation, afraid of sex, fundamentally afraid that he is going mad or will go mad one day. So he comes to this fear without any of the preliminary experience of fear of it. It is, therefore, a tremendous shock to feel afraid of going mad *and* to feel that he is quite right – that in fact he has already gone mad. It is almost like throwing yourself out of the window and finding in mid-air that you have committed suicide; it is too late.

Q: Would you say something more about the 'psychoanalytic calendar', the way in which one can date an occurrence between the patient and his analyst?

B: I think the question is related to this matter of 'vertex'; something which is not clear can become clear if you move off to one side

or the other. For example, you can ask yourself what a problem would look like if you were an Elizabethan, or if you were one of the early settlers in South America. It can often give you a clue as to the nature of that problem when discussion seems to be at an end and further inspection from one standpoint yields no further result.[1]

The same thing can be done by changing, not so much your geographical position, but your position in time. You can look at the matter as if you were using the second hand of a watch. If you were timing an Olympic runner over a distance of a hundred yards you would have to use a watch which recorded split seconds; if it was a marathon run then the watch would have to be a different one. If you were discussing verbal communication the scale would probably have to be tens of thousands of years; if you were discussing the length of time that human life itself has existed on the earth you would have to use a time scale of hundreds of thousands of years. If you were considering where this building would be by the time the spiral nebula of which we are part had rotated enough to carry us to the opposite side of the nebula, then you would have to measure that in terms of cosmic time, in terms of 108 million light years. It is useful to accustom oneself to these imaginative vertices of thought. If we are discussing civilized thought or behaviour we have to consider a time scale measuring the distance between the height of Egyptian civilization and the present day; if an archaeologist is excavating the remains of Mohenjo Daro he has to find some method by which he can place it in the calendar of human history. But supposing you have before you a patient who is a civilized, educated human being and something appears or is uncovered which is curiously anomalous – such as a statement that anybody knows that a violinist is masturbating. How do you date that fragment?

I had the experience in war of discussing with two or three of my friends the feeling that we did not want to go on fighting, that warfare seemed to be ridiculous and stupid. That discussion was extraordinarily similar to another which is clearly described in the *Bhagavad Gita* where Arjuna argues with Krishna and says, "These opponents include many of my best friends, many people whom I admire, who

[1]In the *Mahabharata*, 'dates' are virtually ignored. In psychoanalysis we talk about the past or the future. What the evidence is for such spontaneous dating is not yet clear.

are relatives of mine"; he throws down his weapons and says, "I will not fight".

Many of today's problems expressed by our patients can be recognized as having been problems from the beginnings of recorded time. It is useful, therefore, to have at your disposal your own particular framework, your own psychological architectonic, so that if you are trying to portray the mind with which you are in contact you can date various parts of it according to an already prepared scheme, a grid of your own construction. The Grid which I drew up needs to be improved by you for your own use; it is merely an indication of the kind of thing which might be an aid. The time dimension, which can be measured by watches or clocks or calendars, is only one co-ordinate enabling you to place a finding in space. If you use a large scale then psychoanalysis occupies only a very small part up to the present; it is only a recent off-shoot of the capacity for thought. But the capacity for thinking is itself only a recent bi-product of the development of what we are used to considering as human life. And that in turn is only a relatively recent phenomenon in terms of the development of live objects – plants and viruses as well as animals.

Q: In the sixteenth century Tomé de Souza decreed that for every person eaten by cannibal-Indians an Indian would be shot from a cannon. Thus the whole of the cannibal-Indian culture was destroyed along with cannibalism. What happens to the patient if his destructiveness is 'killed' by the analytic work?

B: The human animal must in fact be extremely destructive because we still exist, we have been able to destroy all our foes such as the animals which might want to eat us. We are still at it; we are still trying to destroy spirochetes, gonococci – minute creatures. But we are also dependent on our fellows. How are we to adjust to 'civilized' life, namely, being part of a civil community? We have to become adjusted to a herd existence, but while there is an impulse to live co-operatively with our fellow animals, at the same time there is an impulse to band together to wage war against another collection of people. There is an impulse to say, "*This* animal looks the same and has the same smell as I have, so I'll get together with it. *That* animal, on the other hand, has a different colour and a different smell – let's kill it". Terms like 'The United Kingdom', 'The United States', and now 'The United Nations', are premature and precocious.

Just how united we are we can see by having a close-up look at these various united states; we usually find that they show every sign of disintegrating. What are we to make of this paradoxical development? For how long could we say that there is a state of unification in the journey from barbarism to decay? For how long could we say that any society of people is civilized between the time when it is barbarian and the time when it is in decay? Sometimes it looks as if a nation goes from barbarism to decay with virtually no phase of civilization between. Of course it does depend on how you define 'civilized behaviour'. In some respects we attach great importance to works of art if a society produces the kind of grave furniture found in the tomb of Tutankhamun. I read recently of a woman who was buried, in accordance with her wishes, seated at the wheel of her Ferrari motor car. What a fascinating archaeological discovery that will be! How should we date the artistic achievements of *that* civilization?

8

Bion: Hitherto we have been discussing matters for which I think there is very little, if any, scientific evidence. A hostile critic could easily say, "This is all pure imagination". I would say, "Yes but I think it is time that 'pure imagination' was recognized as having a place in scientific work. If that is considered to be exclusive we had better reconsider a great deal of what passes for scientific work so that we may be quite sure that some of these extremely prestigious papers could not be classified more adequately as 'science fiction' than as scientific work – in the sense of formulations of the truth to which they are pretending to aspire".

I think it is fair to assume that when a patient comes to us he sincerely means to speak the truth, but he may be unaware of the great difficulties involved. However, *we* should be aware of those difficulties and should not claim a higher status for our theories than is justified by a critical appreciation. Otherwise we could find ourselves trying to defend the indefensible.

To turn now from imaginative conjectures and rational conjectures to something for which I would claim rather more credibility. The language and theories of psychoanalysis are swept more and more into the domains of social discussion. I remember, when I was first at medical school, one used to hear socially about Father Figures, Oedipus Situations and the rest of what I can only call Freud's tomb furniture dug out of Freud's works. It sounded plausible and even learned. Today I think it has become still more widespread. We are all familiar with psychoanalysis which is much 'improved' but which is in fact based on an inadequate understanding of psychoanalytic theories. I think the instincts of psychoanalytic societies are right when so much emphasis is placed on individual psychoanalysis.

I want to draw your attention to a peculiar and doubtful situation which no single analyst can fully investigate – one doesn't live long enough. But if all of us are sensitive to it then between us we may be able to make some progress in this 'obscure domain'.

The patient lies down on the couch and starts off without the slightest hesitation by saying he had a dream last night. I don't want to give the impression that I think he is lying, or that I don't believe him; at the same time I would not assume that that statement is a true one. I would be alert to the possibility that what I am being told is not correctly described by the patient as 'a dream', however sincere he is. Is there any way in which one can be sensitive to the possibility that one is not listening to a dream? Are there any 'facts' in the actual practice of psychoanalysis which make one wonder what one is listening to?

While the patient is telling me his dream I find myself wondering why he should take the trouble to dream it. The account is so literal; it doesn't sound like an imagination; it sounds as if it might easily have happened. That is a subjective criterion; it depends on the feeling that, having listened to a great number of dreams, there is a difference in them which is not simply due to the fact that we are all different individuals and that therefore no two dreams are likely to be the same or even similar. My suspicious are aroused if the dream is recounted without any hesitation, no groping for recollections, great detail and a similarity to an ordinary story. One of my earliest experiences of this was with a patient who started telling me a dream at the beginning of the session and went on and on. I began to feel, "I wish he would get on with it – I shan't have any time to interpret this". The patient may have been trying to deny me time for an interpretation but I did not think so. I contained my impatience and went on listening. And he *did* go on to the end of the session. Finally I had to say, "Well, we'll have to leave that for the present". I think the patient was a bit suspicious that I had not listened to the entire account and surprised when I said it was time to stop and hadn't given him any interpretation at all.

At the next session he said, "You didn't give me any interpretation".

I said, "Perhaps if you go on with the dream we may have time for interpretation today, or perhaps next time". He said he couldn't. But I was prepared to believe that he could go on with that 'dream'; I felt that he had been disconcerted by my invitation to continue. However,

he then went on with free associations as any person who was having an analysis might do. But I did not feel that he was wide awake or that he was continuing with conscious communications. I could put it this way: I thought he was continuing in a different state of mind; a state of mind in which a person is when they are what we call 'awake'; the state of mind in which people are when they are aware that it is daylight. Conversely, the alleged dream is a reminiscence of the state of mind of a person when asleep and probably when it is dark. (Gerard Manley Hopkins wrote, "I wake and feel the fell of dark". "The fell of dark" is a term, somewhat ambiguously used, with an uncommon meaning of 'fell', that is, 'pelt' or 'fur'. So the quotation also means, 'I wake and feel darkness as if it were an animal skin'.)

It sounds as if the patient had a dream last night and it would be reasonable to interpret it according to what one knows about dreams. But the dream that the patient is reporting is different. It has something about it that makes me feel that if I had had that dream then I could feel it in the way I could feel a fur coat.

I don't pay a great deal of attention to the fact that when the patient says he had that dream and recounts it he is awake and apparently in the state of mind in which people call the nocturnal experience 'a dream'. I cannot say that he is hallucinated or deluded; it would be much more satisfactory if I could but I don't want to give you any idea of certainty about it. I would leave you sensitive to events of this peculiar nature so that when they occur in your consulting room you can make your own contribution to what it is that is happening.

I have referred elsewhere to a statement made by Blanchot – "*La réponse est le malheur de la question*" – which might be translated, "The answer is the misfortune or disease of curiosity". In other words, nothing kills curiosity so thoroughly as the answer. A patient who keeps on saying, every time you give an interpretation, "Yes I know, yes I know, yes I know", or "I don't know what you mean", kills further curiosity. You cannot continue to research into that matter; the patient already knows all the answers; or, alternatively, he doesn't understand any answer you give. He equally doesn't know any answer that *he* would give, so both people are in the same unfortunate position. He cannot be analysed; I cannot analyse. To borrow Milton's phrase, "Wisdom at one entrance quite shut out". That sort of behaviour on the part of the patient makes it impossible for you to use your senses; it hurts to listen to it. It is similar to the situation

which arises with the patient who says he has no imagination; the patient who says he has a dream and tells you the sort of dream I have just described; the patient who fatigues and deafens your ears so that you cannot listen to what he says. If I try to summarize that situation I could say that the patient is disturbed, or a borderline psychotic. I would have told you precisely nothing. To try to tell you something more positive I fall back on more imaginative conjecture. I suggest that this same patient is a very good practising psychoanalyst of the sort that detects all my weak points and knows exactly how to play on them. If he knows from what he can see or feel about me that there are certain sounds which I find difficult to tolerate – like "Yes I know", "I mean-to-say", "You know", "I don't understand what you mean" – then he can bombard me with those statements; he can inoculate me with that kind of verbal soporific. As in Hamlet, poison can be poured into the ear so that one's analytic capacity is destroyed. Such a patient, if successful, leaves you a worse analyst at the end of his treatment than you were when you first met. I do not mean that this is consciously deliberate – it is 'a gift'.

These discussions seem to be disjointed because in the practice of analysis the disjointed nature of the evidence is part of the difficulty. You may have bits of evidence which are scattered over the material of a period of some months or more and it is not easy to see that the bits are related to each other. It is particularly difficult because you cannot exclude the possibility that their connection may be in your own mind and not proper to the material.

I want to talk now about one of these instances of what I have called the patient's restlessness. He may talk of having taken up classical dancing, gymnastics, or there may be something more immediately noticeable, namely, his posture on the couch or his wish to change from the couch to the chair, or from one chair to another. It is often unobtrusive. Sometimes the patient may call attention to himself without appreciating the significance of the fact to which he is calling attention. He will laugh or make a joke of it, and may not like it when he finds that you take it seriously. The important point is the fact that the patient is beginning to want to make athletic rather than verbal communication. If, in the formulations which we use as free associations, the patient can give expression to the symptoms, the complaints of which he is aware, then perhaps it is possible that we can use the same channel of communication in the *opposite direction*.

Can we communicate something verbally to the patient so that he can transmit it through his central nervous system, through the ramifications of the autonomic and the sympathetic systems to the address to which we want it to go? If the patient is delivering his communication to you through a system which comes to the surface in a form which we recognize – asthma for example – is it possible to communicate with such a patient so that the interpretation goes through his lungs back to wherever the origin of the asthma lies? In physical medicine we could say we might hope to examine a patient physically and find where we thought the focus of infection lay. Could we find some method by which our interpretation found its way back to the point of origin of what we think is a mental system, like a symptom of anxiety or dread, or terror or panic fear. Frequently a seriously disturbed patient has spent his life in denying any expression to what he suspects is a serious disorder – the sort of thing we could call a psychosis or mania. It is too often forgotten that the seriously disturbed patient is being disturbed because he is aware of something serious, even if his analyst isn't, and does not want to be reminded of it. Analyst and analysand can be at one in wishing to deprecate the seriousness of 'mental pain' – hence a dangerous collusion.

The patient is likely to express his terrifying feelings and experiences in terms which are deceptively faint and unspectacular. So when you hear a patient jokingly refer to having taken up dancing or other physical activity could you find some method by which to communicate through that same system which has shown itself by this faint and hardly perceptible comment?

At the present time I think it is probably wiser to keep to the ordinary, conventional system of verbal communication, to give interpretations as accurately and as artistically as we can. I say 'artistically' because I don't think it is much good producing more and more psychoanalytic journals and papers to a point where we fatigue the eyes of readers. When a new Journal is announced do you feel that your "heart leaps up with joy"? Or do you feel disposed to cancel your subscription? If the latter then I suggest that you don't write any more articles like that yourself.

It is easy to say, but it is in fact difficult not to write the same tedious and inartistic language oneself. I don't in any way claim exemption from the complaint, but I do think that we ought to try to express ourselves so that it is a pleasure for the recipient to receive. Artists

can say disagreeable and frightening things; yet we may be prepared to listen to their music, read their books or look at their sculptures.

Q1. Is there any difference between a somatic and a hypochondriac delirium?

B: Yes, if you think so. What that difference is has to be determined by the validation of the psychoanalyst in the experience while it takes place.

Q2. What would be their clinical and psychodynamic aspects?

B: I should have thought that the 'somatic delirium' refers to the total soma; if it is 'hypochondriac' then I would be inclined to think that it is only related to that part of the soma which is below the chondria. A term like 'hypochondriac' has been so abused that it has come to mean that the person *is* hypochondriac and therefore there is nothing the matter with him. *If* he is hypochondriac, and that is a correct description, then one ought to pay serious attention to that localization.

In English we talk about a 'sweetheart'. {Translated as 'noivo'} No, I didn't say that Portuguese word; I said "a sweetheart". I think a Chinese could say, as a term of endearment, "my heart and liver", meaning a beloved girl-friend or boy-friend. Why these anatomical descriptions? Is it hypochondriac love or somatic love? Ought we to attach more importance to these statements? They are meant seriously by the people who use them. Unfortunately words like 'love' have become so debased that it is difficult for people who *do* love each other to know what language to use or what attention to pay to anybody who addresses them in such terms. Why is it that when somebody says "I love you" to you, you sometimes feel that it is a very important statement that has been made, but at other times you pay no more attention to it than you would to an advertisement for a brand of cereal? There must be something of which you are aware which makes you know that those same words have fundamentally and basically different values according to their context.

That is why in analysis it is so important to be aware of the context in which the words, whatever they are, are spoken.

I often feel that I have to listen to the patient for a long time and don't feel disposed to interrupt and break his train of thought, but if I say nothing because I want to listen, that fact itself can act as an interruption; the patient can say, "Doctor, have you gone to sleep?" The patient is familiar with the fact that people who apparently are listening and paying attention are in fact absent in mind.

A bore, a gifted bore, can leave you no choice except to be absent in mind and then say, "Doctor, are you asleep?" To which one is tempted to reply, "Well, if I'm not, why not?" It is a subtle form of cruelty to be able to be a bore and to demand full attention of the boredom. So instead of making that somewhat frivolous reply it might be better to consider the matter and to draw the patient's attention to the subtle pleasures of cruelty and the experience of being cruelly treated; it is a primitive and basic form of sexual love, and therefore something that requires attention.

9

Bion: We consider that the human individual behaves exactly as if it had some kind of will, or purpose, or government. In the study of the individual cell, individual person who has boundaries which are the same as the boundaries of his body, an attempt has been made to describe that body with names like 'hand', 'arm', 'head' and so on. But once the anatomists and physiologists look into the matter they tell us that they don't know what is meant by 'a hand' because they don't know where the hand starts and where it finishes. We could carry out violent investigations by cutting off a hand or a foot, but it is noticeable that the human cell or individual is never the same when these violent operations are carried out – and the change is striking indeed if you cut off the head. In fact the popular idea is that the dead person is very different from the live one.

That is a relatively simple problem, but anatomists know of 'ghost hands', 'ghosts' of such portions of the body that have been removed. We understand that there is an obvious explanation in the continued stimulation of the nerve endings which previously went to the missing organ. The psychoanalyst's problem is that he is told of pains which cannot be linked with physical structures; we call them 'mental pains'.

The problem exists in part because there is no adequate or satisfactory geography or map of the human mind. Perhaps that is because there is no such thing – it may be a figment of the imagination. But it does look as if the idea that the mind is in some way subject to the same limitations, the same boundaries as the body, can no longer be regarded as true. Through the use of the vocal cords the human creature can communicate with other individuals; the characteristics of one individual can be spread to other individuals.

It becomes clear that attempts to describe the mind – soul, supersoul, for example – are not adequate. Freud suggested the terms id, ego, superego. The Jesuits described an 'arbitrium' which has a function which betrays itself as arbitrating between one part of the mind and another. The problem is open-ended; the more we investigate it the more we have to revise existing theories.

Human individuals are also creatures which hunt in packs or herds and which have many of the characteristics of agglomeration – they form towns and cities. But so do insects like termites and ants who build up extraordinary structures and behave as if they were joined to each other. Fishes, whales, dolphins – they all have a method of communication, as well as those animals that have given up the water medium and have taken to the air. Flying birds seem to move and wheel together; at other times they form what looks like a pattern to us who are engaged on crawling about the surface of the earth. The pointed end of the pattern, a wedge shape, is occupied by a succession of individuals, constantly changing. How is that done? Is the leader giving orders to the entire flight? Or is the leader representing the direction in which the flight is to go? (I use this model to represent the problem of the mind; who or what decides the course the individual should take?) I think that there is a barrier, a caesura, between my kind of animal and that kind of animal, and between ourselves and ourselves. As far as we are concerned, because we are so close to the crowd of us it becomes difficult to see any pattern at all.

In my attempts to investigate the mind, character, personality or individual, I believe that it is possible to see a certain pattern that is not the same as the pattern of the physical body. Sometimes I can detect a curious state in which the individual is what I have to call 'highly intelligent'. I have to borrow these words from various disciplines for which they were invented, to use them from a different discipline – the discipline which is involved in investigating this mind which we suppose exists. I think I can detect people who are so intelligent, who know so much, that the knowledge is too thick to be able to discern the wisdom. It sounds like a paradox; they are too intelligent to be wise.[1] Such people seem to be able to become technically proficient. For example, I have spoken before of the person who can be a technically proficient violinist, but is incapable of

[1]See also Talk 5.

being a musician. So far the human animal has been very successful; its achievements are extraordinary. A quadruped learns to perform athletic feats like walking on two hind legs; it then goes on to increasingly complex technical activities – sexual activities, for example. The individual graduates from the simple discovery of pleasurable sensations on its own body to similar activities which are carried out by two individuals. Religiously trained people talk about two people becoming one, a process which you could call 'at-one-ment'. The more usual pronunciation in English is 'atonement'; the alphabetic letters are the same whether it is 'at-one-ment' or 'atonement'; they are put together in the same order, but they are not the same word. It has been said that 'at-one-ment' is my invention. I say it isn't. Who will be the arbiter?

Someone may ask, "What is the result of the examination? What have you found out after your mental dissection of the human mind?" I can only say that this same investigation, carried out by myself with the help of another self – which is usually the patient – seems to promote growth or development. Therefore the true investigation is a treatment as well as a cure. The discussion is not something dramatic, like capital punishment; a quick solution is always something drastic and apparently finite. A final solution appears to be quick; real solutions require time. The finite leaves no room for development; we are concerned with something which does require space for growth.

To illustrate some of the problems which face us all I take as a method of description a large scale operation – the plight of the 14th British Army which was defeated at Rangoon in 1942. The British in Singapore had previously detached two battle cruisers to support the garrison. Both those battleships, the latest weapons with which the Royal Navy was armed, were destroyed by Japanese dive bombers. The blow was a serious one; the 14th British Army was thrown back in disorder with hardly any arms, weapons or even boots to wear. And there it was besieged – the remnants – at Imphal. There was introduced as commander of the besieged forces a civilian who had joined the Territorial Cadets – a step which was strongly disapproved of by his fellow civilians. However, he liked that voluntary soldiering and became a regular army officer. He saw service in the desert and in the war against the German forces. Much to his annoyance and disgust he was withdrawn and sent to India where he was again withdrawn and sent to command the remnants of the British Army

in Imphal. It was not an enviable post to be put in command of the remnants of a dispirited, demoralized and defeated army.

But this civilian-turned-soldier told his fellow troops that if they were cut off from their base, if the enemy had surrounded Imphal – as indeed it had – so these remnants of the 14th Army could equally be said to have cut off the Japanese from Japan. It was only an idea of course, only an imaginative fiction. However, the character or spirit or soul infected this decayed and destroyed remnant of an army with health. The *idea*, the fiction that the 14th non-existent British Army had cut off the Japanese forces from Japan, started becoming a reality. The British could get no more equipment from Britain because Britain couldn't be bothered with what happened in faraway places like Burma. So they had to march; I don't know what they marched on – their bare feet were hardly enough. It is difficult to say they marched on their morale or on their spirit which had been produced by the injection of this amateur-turned-professional called General Slim.

The Japanese had discovered the secret British code so that they could read all the messages which the army commander communicated to his troops. General Slim, who had a habit of thinking, decided to go on using the same code. Through this code, which he knew the Japanese could now understand, he continued to transmit messages to his left flank. The Japanese naturally concentrated their troops against the left flank of what was a non-existent army – another figment of the imagination. When the Japanese had concentrated their troops against this non-existent left flank, the remnants of the 14th Army, now reinforced by the spirit of General Slim, broke through the weakened Japanese left flank and defeated the Japanese who had nothing to fight but the air. While they were busy fighting a figment of General Slim's imagination the real remnants of the 14th Army found themselves in Rangoon receiving the surrender of the Japanese commander.

What are we to say about this 'spirit', this 'soul' or 'mind'? That is what we are supposed to be dealing with. Does it exist, or does it not? Are we concerned with a figment of our imagination, or is there something behind these words?

I don't know the answers to these questions – I wouldn't tell you if I did. I think it is important to find out for yourselves. When you go to your consulting rooms tomorrow perhaps you will investigate

this matter, and perhaps between us we may ultimately find out what this thing is that had no shape or taste or colour, or anything that our senses can make us aware of. At the same time perhaps you will find out what it is that *you* use to get in touch with this other invisible self. It seems to me that it is real enough to leave room for the development of this 'thing' of which my senses give me no knowledge and for which I cannot find any language with which to communicate it to you.

Who or what breathes spirit into a collection of people and makes them develop? What shape will the Brazilian nation take? What shape could we see if we could see it in the way that we see the shape of a flight of birds? Our view is close up, microscopic, a small part of the whole; what is the real pattern?

Milton, by means of the 'Areopagitica',[1] tried to infuse his ideas into his countrymen; today we can see more of what his ideas were, what happened to them, what happened to his countrymen. Who or what will lead this collection to which we are too near to see and of which we are one 'cell'? The question could equally be posed about the individual who is a group of thoughts and feelings.

Are there too many Brazilians for us to be able to see the Brazilian nation? Perhaps somebody who can will write it down, or compose it musically, or paint it. Or form it into a conglomeration which, like an army, has a structure.

The past is mostly forgotten, the future we cannot see, but is there some seer who could detect the germs of the future? What is a psychoanalyst? What does he do? what has he become? The answer is the disease of, ultimately the destruction of, curiosity. But in the mean-time the question itself may provoke growth.

10

Bion: One of the questions which analysts have often not asked themselves is, "Do I want to be a psychoanalyst?" Men and women have problems that they think are going to be 'cured'; so they go to see an analyst to 'get cured'. The question of embracing the psychoanalytic profession is not considered. It is assumed that they *can* be analysts and that therefore they *want* to be. But it is an open-ended question worth constantly asking yourself. There are other versions of it: Do you want to be a particular person's analyst? Would you like to have another patient? Would you like to have another patient like the last one? You can consider which of the patients that you ever had are the ones with whom you have had the most rewarding experience. It can be something of a surprise to find which are the ones you find most rewarding and what sort of person *you* must be to like that kind of patient. That is another reason for regarding the question as open-ended; you do not *stop* learning something about yourself.

If your central nervous system is in tolerable working order then your senses give you a lot of information. After that what you think that information means is up to you. But that depends on whether you want to know the meaning; you may not. Similarly, there are patients who get a 'nice' sensation from the sound of your voice and possibly from the sound of their own. So analyst and analysand settle into a meaningless debate because it feels so 'nice'. The patient feels something which is analogous in physical terms to being stroked; the one mind has a caressing, soothing effect on the other and the mutually gratifying seduction goes on unobserved by either party – so much so that it is forgotten that the patient has come for help. The patient has forgotten it; the analyst has forgotten it; they are locked in a mutually gratifying experience. It may be a long time before the

patient becomes aware of discomfort. It is as if he had access to some soporific drug so that he cannot tell you where the pain is. Here again it is useful to change the vertex so that if you cannot see the pain from one position you may be able to see it from another.

Sometimes the story that is told you is comprehensible but not illuminating; it may then be useful to consider what is wrong with the story. Why does the patient think it is worthwhile spending time and money telling you that story? Why does he think that you might be interested to hear it? For example, a patient who has been going to the analyst for five or six years goes to a hospital for a physical examination, tells them something that the analyst has been analysing from the point of view of its being a hypochondriacal symptom, and is told that he has a terminal illness. The patient asks for an interview with the analyst or perhaps he asks the analyst to come to the hospital to see him there. The analyst comes into the ward and finds the patient undergoing some form of elaborate treatment for the complaint. The patient pours out a mass of abuse on the grounds that the analyst has been treating the illness as a hypochondriacal symptom.

"If", says the patient, "you knew your job, that symptom could have been treated properly long before it became a hopeless terminal case". As the analyst looks at all the apparatus there is no reason to doubt the truth of the statement that the patient's condition is hopeless; that would seem to be all there was to say about it. What is wrong with that story?

I will give you some idea of how my mind would work on this problem. I don't say it would suit anybody else, but it may help you to find the way that would suit you. If it is true that the patient is suffering from a terminal illness time is short; therefore the best use needs to be made of what is left. If I felt that I was going to die shortly I don't think I would want to waste my time telling a psychoanalyst what a fool he was – I think I would leave him to find that out for himself. So why, out of the small supply of time which is available, should the patient want to see me as the analyst? Either he is being extremely prodigal in the use of the time, or there is some other reason for wanting to see me. What other reason could there be? If the patient feels that I have simply been telling him a series of ridiculously untrue stories, he could hardly be wanting to hear more of the same. On the other hand, if, as is the case with this particular

patient, he has been told stupid and false stories for a long time, he may want to hear the truth. The story that it is a terminal illness is true but irrelevant. What matters is that the 'termination' – like the rest of his life – should be properly spent.

There are many ways of telling lies including the erection of picturesque but useless apparatus. The patient may want to see me because he feels that I have never told him lies; in this desperate situation he is anxious to hear the truth and to tell it – including the hate or love he *really* feels.

I have read a psychoanalytic paper in which the writer said that in cases where death was certain the analyst should give up making interpretations and resort to reassuring and comforting statements. I would not want to be told nice stories, whether they were psychoanalytical or religious or any other variety of pleasurable and gratifying seductions. I think that if I had never known the truth or wanted to hear the truth before, I would want to hear it in a serious situation.

It is questionable whether any patient ever comes to a psychoanalyst unless they feel the situation is desperate; it is usually a last resort when everything else has failed. So in spite of appearances to the contrary the whole weight of the experience when a patient comes to see an analyst suggests that the patient himself feels that he needs a powerful injection of truth even though he may not like it.

What is your assessment of the job of psychoanalyst? I have already suggested that it would not be much use being invited to tell various forms of agreeable lies; nor would I want to terrify anyone by telling him frightening stories about his possibly having a fatal disease. Although it may seem theoretical, or even philosophical, I find it easier to fall back on the feeling that I am called upon to make the person familiar with a particular aspect of truth. I know that is an unsatisfactory statement; Bacon summed it up in a famous essay: " 'What is truth' said jesting Pilate, and would not wait for an answer". But I think that most people know what I mean when I say it is safest to feel that one is falling back on as near as one can get to the truth. At least one becomes part of a distinguished company of scientists, painters, musicians and other artists; they are all attempting to display some aspect of the truth. I say 'all'; I mean all those who belong to the distinguished company. Imitation musicians, imitation painters and scientists there are in plenty. There is something unsatisfactory

about the imitation, and if it is unsatisfactory to oneself it doesn't require a great deal of imagination to suppose that it would be unsatisfactory to a patient who is in a desperate situation.

The truth. What does it look like? Who wants to be confronted with a *trompe l'oeil* representation of Paradise? Such confections are pardonable to an agent selling us our earthly home, but not for our eternal home – our Self. In every job the first stage is an imaginative conjecture. The engineer building a dam has to have an imaginative conjecture about where the dam would do the most good, or where it might do the most harm if it were badly built. Later, the imaginative conjecture might become a rational conjecture; the secondary plan might be more workable than the first. In analysis one's first guess as to what the patient wants could be replaced by something which could be drafted on a piece of paper. Ask yourself what these various stages are before you would be prepared to turn these conjectures into a picture in your own mind of what you think the effect would be if you said something to that particular patient.

I think that a revised Grid – not to take the place of the first one – would be useful for a practising analyst to be able to consider how 'a pattern emerges'.[1] I find it useful to consider that the stages are an imaginative conjecture, a rational conjecture, a pictorial image – the sort of thing you can see in dreams and even 'paint' in a verbal version of a pictorial image. That also might come into your grid as part of the progress from O – when you know nothing whatever about the patient – and one tenth or one hundredth of a second later when you begin to have an idea of who or what has entered your consulting room. A minute later the shadowy impression might become more solid, 'three-dimensional'. You can invent this grid for yourself – the one which seems to come closest to your actual experience in analysis. It could also be applied to a scientific paper or to a lecture. The criterion, whether it is true, should also apply, but this time to something which is more aesthetic, as if you were engaged on a work of art. A scientific paper should remind you of real people; it should not be so boring, so unaesthetic that it becomes a pain in your mind to read it. We have a difficult job; even the impromptus in the analysis, the interpretations that we give, would be all the better if they stood up to aesthetic criticism. I hope that does not sound too much like Satan

[1]See beginning of Talk 1 – reference to Freud quoting Charcot.

rebuking sin – I am well aware that my own interpretations, spoken or written, cannot pass these tests. But there is no reason why yours should not. You do not have to be limited by the limitations of your lecturers, teachers, analysts, parents. If you are, there is no room for growth.

THE TAVISTOCK SEMINARS

1976–1979

The Tavistock Seminars, edited by Francesca Bion, was first published in 2005 by Karnac Books, London.

The Tavistock Seminars

BION SEMINARS AT THE TAVISTOCK CLINIC

During the summers of 1976, 1977 and 1978 we spent some weeks in Europe, dividing the time between London, Italy and France. In 1979 we visited London twice – in March and again in September on our return from almost twelve years in California.

While in London on those occasions, Bion was asked to hold seminars at the Tavistock Clinic – fourteen in all. Unfortunately the few surviving video recordings came to light only recently and are of variable quality. Nevertheless, these survivals give a clear picture of the areas of analysis that were of major, continuing importance to him during the last four years of his life.

Transferring the recorded word to the printed page is by no means a straightforward process, especially if the speaker expresses his thoughts extempore (as Bion always did). At the same time, it is necessary to aim to retain the style and personal characteristics of his written work. Any changes I have made are in accordance with this aim.

Francesca Bion
2005

Seminar 1

28 June 1976

[*This was the year of the record-breaking heatwave and drought. The videotape shows Bion wearing a short-sleeved, open-neck shirt rather than his usual long-sleeved shirt, bow-tie and jacket.*]

Bion: It took me a very long time to realize that the actual experience of being psychoanalysed was a traumatic one, and it takes a long while before one recovers from it. In physical medicine you usually have to go through a period of convalescence; you then hope that if you are fortunate you will reap some benefit from the violence that has been done to you physically. I was introduced to the kind of idea that violence is not done to you by psychoanalysis – that in the course of time you gradually got more and more cured. That doesn't seem to me to fit in at all; it was quite a long time before I began to feel that I knew where it was "at" and what sort of niche I occupied in this peculiar universe or domain that we call "psychoanalysis" – for want of a better word. But I can't say I have got very far with that particular line of thought. Part of the difficulty is that one has to borrow the terminology from all sorts of sciences, religions, aesthetic activities, in order to attempt to formulate a language of our own. There isn't a suitable language for this extraordinary domain, but I am convinced that there *is* such a domain, that there really is something which it is fair to call a mind, or character, or personality. The problem is having to use a debased currency, a language that has lost a great deal of its value and has therefore lost its cutting edge – in so far as one has to use it for a particular purpose.

Freud described the situation in which people suffer from an amnesia – a gap, a space where there ought to be some sort of memory – and then fill this gap with paramnesias. That's fine, and a very

profitable sort of idea it has been. But after a time when we get more and more accustomed to hearing about psychotherapy, psychoanalysis, the more we wonder whether there isn't another great gap – not amnesia – the vocabulary is so difficult we don't know what to call it. But anyway, when we are at a loss we invent something to fill the gap of our ignorance – this vast area of ignorance, of non-knowledge, in which we have to move. The more frightening the gap, the more terrifying it is to realize how utterly ignorant we are of even the most elementary and simplest requirements for survival, the more we are pressed from outside and inside to fill the gap. You can do that perfectly well – with art, with religion, you can multiply theory. You only have to ask yourself what you do individually in a situation where you feel completely lost; you are thankful to clutch hold of any system, anything whatever that is available on which to build a kind of structure. So from this point of view it seems to me that we could argue that the whole of psychoanalysis fills a long-felt want by being a vast Dionysiac system; since we don't know what is there, we invent these theories and build this glorious structure that has no foundation in fact – or the only fact in which it has any foundation is our complete ignorance, our lack of capacity.

However, we hope that it isn't completely unrelated to fact that psychoanalytic theories would remind you of real life at some point in the same way as a good novel or a good play would remind you of how human beings behave. Leonardo could draw things that remind you of what human beings look like. If you look at his drawings of hair and turbulent water in his Notebooks, there is an attempt to give an aesthetic representation of the sort of turmoil I have described.

Without wanting to forget all that – the fact of our ignorance and the fact that we have to try to make inroads into this universe in which we live by these various methods – scientific, religious, artistic – we can go on multiplying the number of approaches that we as individuals make, our own small contribution to scratching a little space into this great mass of material that we don't know.

I suppose it was permissible for biologists and others to talk about sex, but remember the furore that was created by Freud's suggestion that sex played a great part. The fact that he was able to do this also had the effect of making us see most of the development of psychoanalysis in terms of biological effect. Appropriate to that is the work of Mendel and his promulgation of the laws of inheritance.

Of course, it begs the question when we talk about "Mendelian inheritance", because it is tautological. However, I think a rather awkward situation arises when it comes to supposing that there is such a thing as a mind, that we all have a mind or soul or psyche, or whatever you want to call it. We have to talk like that because we haven't a proper vocabulary for it. As soon as we recognize that, there is some gap there that isn't in fact quite empty. The borrowing from biology begins to break down when it comes to the question of the mind and the transmission of ideas. In fact, we have to consider that in addition to this biological inheritance, this Mendelian myth of propagation, it becomes one that applies to the world of ideas in which characteristics are transmitted from one generation to the next, or to some subsequent generation. We could say that on the one hand there are the genotypes, the genetic inheritance, and on the other the phenotypes, the transmission of appearances. I used to be taught to believe that these acquired characteristics are not transmitted – the only characteristics that are transmitted are the Mendelian ones, the genetic ones genetically transmitted. I don't think this is good enough; I think there is something quite unmistakable about the way in which *ideas* are transmitted. The individual gives birth, so to speak, to some other individual who bears signs or symptoms of these phenomenes – I am inventing a word to describe these particles that continue to be passed on, so that you can imagine a situation in which there is an English nation affected by Shakespeare and then the characteristics become, as it were, somehow transmitted – not altogether in an obvious way that you would suppose, by books and so forth. I remember John Rickman telling me about his experience at York railway station when a soldier came up to him and said, "Sir, weren't you at Northfield?" Rickman said he was. "It was the most extraordinary experience I ever had – just like being at university", said the soldier. That man hadn't a hope of ever getting to university – as far as we know. His educational and financial background, his cultural background, were all against him. So it was probably the only chance he had had. I don't know why, out of all the people at Northfield, that idea was transmitted to that particular person and changed his outlook – it certainly sounded as if it had. Whatever may have happened to all the pampered darlings of my generation at Oxford and Cambridge, they could pass through university without having the faintest idea of what a university was. But one man,

who couldn't possibly know what a university was, almost certainly did. We are led to suppose that something happens to an individual, and then that "something" gets transmitted elsewhere; but the laws of Mendelian inheritance don't apply – some other laws do, such as phenotypes and phenomenes.

We can look at it very closely and in great detail, as in psychoanalysis. But I am not sure that the increased depth of observation that becomes possible when one is closely in contact with another person will tell us very much about this other form of transmission. Indeed, it is very difficult to know what effect an analysis has on the individual anyway. Some people certainly seem to be able to turn the experience to good account. But I think that in many cases it is purely ephemeral – there is apparently a "cure". We can use a term like "cure", but it has no lasting reality, no particular significance – in contrast with the basic, fundamental characteristics transmitted according to Mendelian laws. We could say, "That, Exhibit A, is a human being; that, Exhibit B, is a tiger, a cat, or a sheep." It would seem as if there are certain fundamental things that follow the laws of Mendelian inheritance. The other laws (if there are any) have to be discovered. It is possible that if you take a group of people – say, like those at Northfield – you might in the course of time be able to detect what sort of course is pursued there by an idea, by something that would seem to be a part of thinking. That is where people who observe groups may have a chance of seeing some of this form of inheritance.

To get back to the psychoanalytic view: it is quite useful to talk about "transference" and "countertransference". Or, as Winnicott puts it, the transitory object; it is in transition, in passage from goodness knows where to goodness knows what, from oblivion to amnesia – the tiny little bit in between that could be filled up by saying "transference relationship" and "countertransference", but I think it will have to be filled in with something else. Because the relationship of these little packets cannot be so easily determined, you may be able to see an idea zigzag its way through a group. I don't know where the idea comes from and I don't know where it goes to, but it may be observed *in passage*. This is where you get back to the practice of analysis and the practice of group observation.

Q: [*inaudible*]

Bion: Pain is a fact of existence – not so very different from pleasure. Indeed I think that one requires a terminology in which there are not specific words so much as concrescences; a number of feelings or ideas get collected together and could be put into some sort of order. You could regard pleasure and pain as different ends of the spectrum.

It is quite easy to see why we like to have a nice feeling and even to believe that it is possible to have a nice feeling by itself. I think it is rubbish; you have to suppose that either you have feelings or you don't. If you are not willing to pay the price of the inescapable fact of pain, then you get reduced to a situation in which you try to isolate yourself. Physically it is quite possible: you can draw the blinds, turn off the light, have the telephone cut off, stop reading the newspapers and keep yourself in a situation of complete isolation – *physically*. Mentally, I don't think it is quite so easy. For example, even if it were possible to go back into the womb, it is very doubtful to imagine that one would be completely isolated so long as one continued to live. The human foetus lives in a fluid environment, the amniotic fluid, and embryologists say that it has these auditory and optic pits. At what point do they become functional? There is no reason why they shouldn't become functional, even to the foetus, because a watery fluid does transmit pressure. I think that, at some point, the foetus can be so subjected to these changing pressures that long before it changes from a watery fluid to a gaseous one – the air, birth – it does its best to be rid of the whole lot.

I think it would be a complete distortion of Kleinian theory to suggest that even a foetus might resort to splitting off thoughts and ideas and phantasies, and evacuating them into the amniotic fluid. However, I don't see why we shouldn't indulge in these phantasies. Freud said, "I learned to restrain speculative tendencies and to follow the forgotten words of my master, Charcot, to look at the same things again and again until they themselves began to speak" (1914d, p. 22). I have great sympathy with that, but I think it is dangerous to imagine that we can do without these speculative adventures. Some sort of discipline is required.

It seems to me that if you consider what appears to be this curious progress from something like the fishy existence to the amphibian existence to the mammalian existence, there seem to be these archaic survivals. A surgeon will say, "I think there is a branchial

cleft tumour." It's a survival, an archaic part of the body that proliferates and becomes dangerous. There's a vestigial tail, and that begins to produce a tumour and requires an operation. It would be nice, so seductive, if the mind, this archaic survival, could be so easily detected – but it can't. We don't seem to be able to smell it, touch it, feel it or see it, and yet we are aware of it. Unfortunately we can only say that perhaps we are completely mistaken: we are being stimulated by something or other, and then we build up this elaborate system of paramnesias, these elaborate systems of theory, because it is so much quicker, so much nicer to be able to fall back on theory. If I am right about this, then I think we could say that as far as mental life is concerned, we are in our infancy, we simply don't know what development is likely to take place or whether the development will be terminated by our magnificent equipment of simian capacity – being able to produce nuclear fission and blow ourselves off the earth before we can develop much further.

Q: [*inaudible*]

Bion: Living in a watery medium, one of the foetus's long-distance probes is its sense of smell. Dogfish and mackerel can detect decaying matter at a considerable distance – in a watery medium. Transported to a gaseous medium, the individual carries a certain amount of the watery medium with it – mucous, saliva and so forth – and can therefore continue to smell things that are not completely desiccated; the watery medium that was once outside is now inside. Some people can be very sensitive to that; they don't congratulate themselves on their capacity to smell things that other people cannot, but complain bitterly of "nasal catarrh", talking exactly as if they feel afraid that they will be drowned by it. In short, this "catarrh" which could be an asset becomes a liability of which the individual is terrified.

I think this also applies to the eyes that show you things even if you are not in physical contact with them, and may indeed show you things that you don't like to see at all. . . . It is possible that we have hit on some measures by which we can develop our mental capacity. This is probably quite all right provided that it is more or less harmless. But suppose it becomes really penetrating; there is a mediaeval drawing of a person shoving his head through a sort of adamantine shell and is then able to observe the universe that lies outside. If astronomy actually enabled the individual to penetrate into space,

then there might easily be an objection to that – a violent objection against all these radio telescopes and so forth, a wish to destroy them all because they made life so uncomfortable – it is so much nicer to be blind and deaf.

What it means, then, is this: are we going to dismiss X by saying, "Oh, he's terribly hypochondriacal" – finish; we thank God we don't have to bother any further? Or should we listen to what he says? Should we expose ourselves to what this individual is trying to communicate?

Freud said that we should pay attention to dreams. That has quite a history – lots of people have said it before, but Freud carried it to very great lengths, suggesting that we should have real respect for what we see and hear and experience when we are off our guard as we are when we go to sleep. There are very few individuals who have any respect whatsoever for the continuation of those dreams when they are wide awake. They are not even likely to admit to having them, because they know that the rest of us will call them hallucinations or delusions – as we all know, the authorities in some places are at pains to shut people up where they can do little harm – inside mental institutions. It is another future that lies before psychoanalysis likewise: to disturb the authorities and help them to imprison the human mind to keep it in a harmless condition. In a way we feel that it is all very well for people like Picasso or Solzhenitsyn – they were great men, and it was reasonable for them to put up with that sort of thing. But it is awkward to think that we, with our ordinary capacities, might have to stand up against it to support the movement towards freedom of mind, the movement that might aid development and discover the rules of mental nutrition. How do you feed the mind in such a way that it can develop, not get poisoned?

This is fairly easily discernible when it comes to a question of the application of drugs of one sort or another – alcohol, soporifics and so forth. But it is not so easy to know what *ideas* are soporific, what *ideas* are poisonous, and whether we, as analysts, are not furthering these developments of methods by which thought would become impossible.

André Green drew my attention to this statement: "*La réponse est le malheur de la question*" ["The answer is the disease, the misfortune, of the question": Maurice Blanchot (1907–2003), *L'Entretien Infini*]. In other words, the answer is the thing that will put a stop to curiosity

better than anything. If anybody is at all curious, you can stuff an answer down their throat or into their ears and that will stop them doing any further thinking.

Q: [*inaudible*]

Bion: The impression I get about morality is that it is basic. I have been struck by the fact that making a faintly disapproving noise will cause an infant to shrink back as if something very terrible has happened. I don't get the feeling that there is any conscious idea of what the crime is; in fact, the nearest that I have got to Melanie Klein's statement of it is, "free-floating anxiety". It is an anxiety without any concept attached to it – so much so that I think the growing creature does its best to find a crime to fit the feeling. So there is no difficulty about rationalization, no difficulty about having rational feelings for regarding someone as a criminal or thinking of oneself as one. And if the worst comes to the worst, the person can always commit a crime to match the feeling, so that the morality will actually precipitate the crime as a kind of therapeutic attempt; the person concerned can feel, "Yes, I may feel guilty, but who wouldn't? Look what I have done." In reality, I think that someone can really commit a murder in order to be able to feel that at least his murderous feelings of guilt are rational. But all this usually means is that the so-called rational event is one that we are capable of understanding according to our logical rules. That is a matter of our human limitations – it has nothing to do with the universe in which we live. Another trouble is the sense of guilt that can be so enormous that the person concerned tries to get rid of it, tries to embrace a sort of theory or idea that is absolutely amoral.

Q: [*inaudible*]

Bion: Nearly everybody has been taught to bother about other people, to be concerned for them. That can also be one of these tricks learnt in the course of one's life – how to be *just like* a loving or affectionate person takes the place of *becoming* one. That is one of the solutions that put a stop to growth and development.

In analysis you have to be sensitive to the situation where the patient is talking very clearly, very comprehensibly, about his concerns for this or that cause or institution. In crude situations it is fairly easy to detect – yes, he is terribly concerned for the unfortunate people in – somewhere quite a long way away (there is no

danger of having to do anything). So you begin to be suspicious that he is being just like a concerned person, just like a doctor, just like an analyst – and so forth through the list. But at some point it can become clear to you that a change has taken place: the patient is, in fact, bothered by something he *can* do something about. Then it becomes important to be able to draw his attention to this: that while he is talking in the same way as yesterday, or last week or last year, it doesn't sound as if that is the case. Of course, you do not want to be flattering, but the patient is much more likely to believe that you are saying this to suggest some improvement.

Q: [*inaudible*]

Bion: When, in the course of the analytic experience, a change takes place, then you can say, "I think you are now feeling that you *are* the father (or the mother)." That might appear to be quite plausible for a person of about twenty or forty, but it may be more difficult to see that a child of six or seven is really a mother – only prevented from being one biologically because she isn't sexually mature. But later development of mature sex and real maternal feelings can be felt to be precocious, out of phase; the child then hates these maternal feelings: there is no chance of her becoming a mother – she just has to go on living another ten, twelve, fifteen years before she has babies. So by the time the really maternal person has a baby, she will have dropped the fancy of being maternal and has become sick to death of it. The human individual is a very defective creature. The snag is that there is nobody who can do anything about it except ourselves.

Q: [*inaudible*]

Bion: The individual has to live in his own body, and his body has to put up with having a mind living in it. So in a sense the analytic procedure, if effective, could bring these two into some sort of harmony with each other. I think it is fundamental that the person concerned should be able to be in good contact with himself – good contact in the sense of tolerant contact, but also in the sense of knowing just how horrible he thinks he is, or his feelings are, or what sort of person he is. There has to be some kind of tolerance between the two views that live together in the same body. It seems to me that that is a preliminary to being able to extend it outwards to a situation where, if you can tolerate yourself as a father or a mother, you might tolerate

a mate who is not you, who might be the other parent. It becomes easier to find the father or the mother for your children as well as your husband or wife.

As I say, I think the first aspect of this is getting into contact with yourself, because so many years are spent in which the individual is "morally" trying to be better, trying not to be a naughty boy or a naughty girl – you can hardly say, "I'm trying not to be a horrible foetus." So in spite of these attempts to evacuate, to give birth to, all one's horrible characteristics so that one remains the ideal person, it is in fact necessary to get to a point where you can tolerate living with yourself as a preliminary to where you can tolerate living with somebody else who will enable you to become complete, enable you to fulfil the biological function where the unit has to be a couple.

Q: [*inaudible*]

Bion: At Northfield, where we had a marvellous programme – a wonderful affair – you could see where everybody was at any hour of the day or night – provided you didn't go and have a look. I remember collecting some men who were on fatigues sweeping the wards; I said, "Come along, let's go and have a look." First of all, we went to the carpenters shop – that was closed. Then we went somewhere else – no, they were on fatigues, so that wasn't operative. There wasn't a single department in this marvellous programme that was in operation – not one.

The tendency is to cut out all these intermediate phases, get to the position of authority and then add the authority formed into a kind of hard shell; no idea can penetrate that authority, no idea can penetrate that shell formed around the personality, the group or the community. Nothing short of a revolution, nothing short of violence, will crack the shell and release the people within it. That is why I sometimes say that an institute is dead: it can always obey rules and procedures; it can be flexible, and the rules can be altered to accommodate to the growth within. But the institute is always composed of people – and there is the trouble: the shell can be so thick that they cannot develop inside it.

Seminar 2

4 July 1977

Bion: I find it extremely dull having questions answered that I haven't asked. So I think it would be preferable if I give you a rough idea of what I propose to say, and then if you will ask any questions you care to. I don't say that I shall answer them, but I can usually find a few more questions to ask you – a natural development, because most questions cause a whole lot more to occur. We never seem to get to the point of an answer unless we look back on it and think we have apparently gathered some kind of experience in the meantime.

I feel disposed to consider this kind of work from the point of view of the analyst: I mean by that the person who is theoretically responsible for the conversation. I am thinking of Freud's constant reference to Charcot's insistence on observation – that seems to me to be the absolute essence of it: observation. But what are we observing? Even the language we use is not adequate for the sort of difficult job that we do. We have to use the word, "observation", as a kind of metaphor, an approximation. In *Paradise Lost*, Milton talks of the situation in which he cannot fall back on his eyes because he is blind; he says he hopes he will be able to "see and tell of things invisible to mortal sight". We cannot hope for that, but somehow we do observe things that are very often not observed in the ordinary course of social intercourse. It would be useful if we could formulate in our own minds what it is that we are observing; it is a question which crops up all the time if we are doing this kind of work. Therefore, it needs to be kept in constant repair. How would you formulate it if you were trying to convey it to somebody else? What form of words would you use? It is curious that we do, in fact, resort to words; it is probably partly because the ability to talk articulate language is our most recent acquisition. But, of course, we are having to borrow words that have been used and

formulated for quite other purposes, when the kind of thing that we are wanting to use them for now wasn't even over the horizon.

Having become as clear as you can as to what in your own experience you are really observing – never mind the books or what you have been told or anything of that sort – and having agreed that what you are going to use is verbal articulate communication, then decide what words you propose to use and draw up your own individual vocabulary. The words we have to borrow are like coins worn so thin that we can't read the superscription on them; we don't know their denomination and we don't know their value. To change the metaphor: it is like a surgeon who has to sharpen his scalpels both before *and* during an operation.

If we cut down our vocabulary to a minimum, then I think there is some chance of finding our own way of using the words to which we are most accustomed. And there is also a chance that analysands will gradually learn how to speak the language we are speaking, whether it is English, French, Italian or whatever. If you go on using the same words with accuracy – *your* accuracy – the patient has a chance of understanding what the words mean. Take, for example, a word like "sex"; it is borrowed from biology and is used by us as if it really meant something. If we were simply dealing with anatomy and physiology, I think it would be possible to use that word fairly correctly. When it comes to using it in what one considers is a mental sphere – assuming that there is such a thing as a mind or a character or a personality – then it becomes quite a problem as to where a person "leaves off", what are his edges.

Freud speaks about the "impressive caesura of birth" [*Inhibitions, Symptoms and Anxiety,* 1926d (1925)], and it is true; I find that people are tremendously impressed by that word [birth] and, curiously enough, also by the word "death". Both of them, of no importance whatever, are inevitable. There is really nothing to be said about them, but they are so impressive. For instance, you will hear something like this: "Will you come and look after these people in this particular ward of the hospital – they are terminal cancer patients." Terminal cancer: you only have to think about it to realize what a ridiculous phrase it is. How do they know it is terminal? Terminal of what? What is it the end point of? And in any case, we are not really concerned with funeral arrangements or something of that nature. What we are concerned with are living people, and if there is a job to be done for making the

lives of people in a particular ward bearable for such time as they have to live, then there is something to be done. That has nothing to do with "terminal cancer"; it has to do with making such life still to come, still left over, still "in the bank" so to speak, tolerable and available, and finding some method by which patients can be given a chance of getting onto that wavelength where you bother with what *can* be done and don't bother overmuch with what you can't do.

I sometimes think there is almost an occupational neurosis of analysts, because so much time is spent in finding out the various mistakes which are made – our faults, sins, crimes and so forth – that we forget it is a very unimportant part of the whole story. We no doubt want to know what we are bad at – it is quite useful to know that – but the really important thing to know is what part of it we are any good at. So even if you have a patient who is supposed to be in "terminal stages", what is he still good for? What would you do with geriatric patients?

At the other end of the scale, people say, "It's no good to psychoanalyse a child of two or three or five." I have even heard fantastic statements about not being able to do anything when "the fibres are not myelinated". The trouble with the myelinated fibres is that the person who has them is often so rigid, so structured, that you can't get another idea through their myelin. On the other hand, if you have a reasonably intelligent baby and quite early in the proceedings you put it on a potty, its non-myelinated bottom seems to know what to do and then proceeds to perform very adequately without any fuss or bother. Why that is, I don't know, but I think the infant must have a personality – and so must old people, however ill they may be, however convinced they are that they have reached their terminal position. If they have, there is no problem. But there *is* a problem in that little, tiny gap of whatever it is – days, weeks, months between that point and the point at which they no longer exist.

Once again, we have to get back to considering that we not only have an anatomy and physiology but also a mind. "Canst thou not minister to a mind diseased?" – the question asked by Macbeth referring to Lady Macbeth sleepwalking. The answer would presumably have to be something like, "Well, not at the moment, but in four hundred years come along again and I'll tell you what we can do." Similarly today: "Come along again in four hundred years and we'll give you an idea." But in the meantime, each one of us lives this

very short, ephemeral existence in which we can possibly use this hypothetical "mind" I am talking about to contribute something to the general fund.

There does seem to be some kind of inheritance of ideas or character or personality. It is not very much good falling back on the ordinary, accepted rules of genetic inheritance; we have to reconsider whether these *acquired* characteristics are not, in fact, transmittable. Then comes this point of how we are to transmit them.

I would like to consider the patient you will see tomorrow. I have a great advantage because I know nothing whatsoever about it, so I am not so easily misled as you, who probably think that you saw or heard that patient today. But I suggest that while it has its advantages, it is also a bit of a nuisance because it stands in the way of the fact that the patient has gone on living and thinking and will not be the same patient tomorrow as today – or at the end of the session as at the beginning. This point is curiously difficult to grasp in the actual practice – and that is what I am trying to talk about here. I am not very interested in the theories of psychoanalysis or psychiatry or any other theories; the important point is what I call "the real thing", the practice of analysis, the practice of treatment, the practice of communication. The question which then arises is: how are you to speak to this patient, the one you have never seen before but are liable to think that you have because you saw him yesterday? The difficulty is this: when you are dealing with a mind or character, the boundaries are not so clearly marked as they appear to be when you are dealing with the anatomy or physiology.

To fall back again on established usage, we can talk about the past, about infancy: in infancy the patient felt such-and-such, had this-or-that trauma and it had this-or-that effect. That is very useful if you consider the patient as developing in a line: born–married–died, *hic iacet*, finished. But the patient you see tomorrow is not like that; you don't see somebody who is "born–married–died". It is very difficult indeed to see what goes on between the beginning of the session and the end of it. One reason for this is that the noise is so deafening, the information we are constantly bombarded with through our auditory apparatus is so deafening. You know so much about your history, so much about the patient's history, so much about psychoanalysis, medicine, physiology, music, painting and so on, that it is very

difficult to detect this "thing" that we are really observing – or wanting to observe. That is one reason why I think it is easier to "forget" what you know and "forget" what you want, get rid of your desires, anticipations and also your memories so that there will be a chance of hearing these very faint sounds that are buried in this mass of noise. I imagine that even a new-born infant has to do this: when it opens its eyes and is suddenly presented with masses of facts by its optic apparatus, then there has to be some sort of selection. This also applies to us from our angle.

Freud pointed out how important it is not to indulge your imagination, to stick to facts. I entirely agree with that – and am constantly contradicting it. I say to people in a supervision, "Look – when you are with a patient you have to be careful what you say. I am sure you ought to give the correct interpretations, but not here – here, I would like you to give your imagination a bit of exercise. So, say anything, however silly, idiotic, stupid, unjustified it is. Then, after you have said it, we'll get onto another point – 'what is the evidence?' – and so on. But in the meantime, cut out all of that and concentrate on what you imagine – speculative imagination, speculative reason." I know the objection to it: it is said that you can imagine anything you like, and certainly reasons are so common that they spring up like brambles. If you are hunting for the Sleeping Beauty of Truth, the difficulty is to cut your way through all these brambles. But I only have to say, "Give your imagination rein", to be reasonably sure there will be silence for the rest of the hour – nobody dares to speak, because everybody believes there is a psychiatrist knocking around the place waiting to tell them the correct interpretation, or to do the correct thing – which is probably to shut them up in a mental hospital or bring them under restraint in some way or another. The result is that their imaginations atrophy and become what I would call "sterile".

When you have forgotten all that you can about your patient – who will do his best to remind you – then you may have a chance of penetrating this impressive caesura of knowledge, facts, and a chance of hearing these very small things that are so difficult to hear or see. In other words – falling back on a rather metaphorical use of language – give yourself a chance to observe the growth of a germ of an idea. That germ may look very odd indeed until it has taken shape as an idea that can be articulated.

I would be very glad if my patient used any language he could mobilize – if I were qualified to understand that language. For example, if I say to the patient, "Where did you go last night and what did you see?", he may be very anxious to insist that he went to bed and went to sleep. [See also Seminar 6.] I say, "I don't mind what you did with your body. Where did you go and what did you see?" Presumably a person who is a very good artist would be able to say, "I'll show you", and would put a line on a piece of paper around that idea, and then he could show it to me. If the person was musically gifted, he could even make black marks on paper and call them "crochet rests" or notes on the stave of music. To me, they don't mean a thing, but I am assured by some people that they can read a score; and when they say that, they mean they can hear the noises. Incredible, isn't it? That is the sort of thing we have to deal with – facts which are incredible. That is the fascination of this job; if one can get through to a fact, it takes a lot of believing – no fiction can touch it.

As I say, it would be very much to my advantage if I could understand music, but the patient is restricted by having to talk to a person who has a limited command of articulate speech. So he has to do a lot of work to tell me what he knows – namely, where he was last night and what he saw.

Q: [*inaudible*]

Bion: From the point of view of the analyst, you have in front of you somebody whose anatomy and physiology can be quite important. You may think, "This patient looks ill", and if you think about it for a greater length of time you may be able to define in your own mind what you mean by "looking ill", what an "ill" person looks like. A good physician will say, "Ah, that patient has a cachectic flush", and then from that point he can interpret what that particular flush means. Physicians usually call these things "diagnoses", but in fact they are interpretations – interpretations of the information brought to them by their senses. What information is brought to your patients by *their* senses one doesn't know, but you can get an idea of what information is brought to you by *your* senses if those senses have a chance of seeing, hearing, smelling whatever it is that does present itself; and then you can try to transcend those senses to find their meaning, their origin.

Putting this very crudely: in an analytic situation there is the analyst, a patient and a third party who is watching – always. So there are three people anyhow; very often there are others, much more shadowy – relatives, husbands, wives, fathers, mothers, children. Those "objects" – I use the vague word deliberately – exert an influence. So I am aware of something I call "hearsay evidence", the evidence I hear said, and I rate that very low indeed. If I try to evaluate it, I could say that the evidence I get from my senses while the patient is with me is worth 99, and all the rest share the remaining 1 between them; it is of such a low order that it is hardly worth bothering with. I can hear all kinds of things the patient has heard about me, has been told or believes, but what I want to hear is something that is buried in all this noise.

Physicians and surgeons are quite used to considering the findings of the embryologists who think there are signs in the human body of vestiges of different kinds of life, like an amphibian stage. When it comes to the mind, I think it is something similar; what I want to notice, if possible, are the vestiges, the remnants that have succeeded in surviving in the mind of a particular person. Buried somewhere in all the noise that is brought to me by the senses of sight and hearing, and what the patient is saying, including masses and masses of theories of medicine, psychoanalysis, painting, music, there is a vestige of something that is still operative. So if the patient actually turns up and there are two people in the same room at the same time, then you have a chance of seeing what may be these very faint signs. And perhaps, after a time, they will begin to fall together and form a pattern, and the pattern itself will form in such a way that you may be able to translate the impression that you get into articulate speech. It is complicated because we would like at the same time to be able to say something the patient could understand – and that is very difficult. First of all, it is difficult to get clear what one understands oneself, because of having to fall back on a debased form of communication, so devalued that it is hard to sharpen up the words enough to give them some kind of meaning.

So while there are apparently only two bodies in the room, I think we have to go beyond that and detect this third – at least – detecting what *it* detects. The analyst is being analysed all the time by this third party. After a while, if you are fortunate, even the patient gets

this third party brought home to him enough for him to be aware of its existence.

Q: I would like you to expand on what you mean by "at least" a third party.

Bion: Freud says it is essential in an analysis to lay bare the Oedipal situation. There, he is falling back on a verbal transformation of a visual image of three parties. I don't think it is enough. People also talk about omniscience and omnipotence; when you do that, you have brought in still more parties. I don't think it is reasonable to give an interpretation unless you feel fairly convinced that *you*, at any rate, have evidence of the presence of this third party, and then fourth or fifth and so on.

Melanie Klein said that the infant splits up the object into fragments which are then evacuated; she described this as an "omnipotent phantasy". But there can be a situation in which the patient has got rid of, to the best of his ability, all the senses that are disagreeable or unpleasant. For my part, I feel that I have good reason to think that this process takes place even before birth; the patient could be said to have ideas of which he has *never been conscious*. Of course, that is hopelessly contradictory, but then I am having to use language when I'm awake – articulate language. I don't think that Freud, in talking about the interpretation of dreams, really considers the fact that the patient who has a dream had an experience in what I would consider a very different state of mind from that in which he is when he is awake. Therefore, the story that the patient tells you, consciously, is *his* version of what happened last night, but he doesn't really know. I think the theory of the conscious and unconscious – which is extremely useful and, like all these things, becomes a bit of a pest after a time because it gets in the way of being able to see other things that one doesn't know – stands in the way of one's own ignorance, so that there is very little chance of investigating this realm of ideas that have never been conscious and this state of mind that is not available when a person is talking to you with all his wits about him in broad daylight, and you are listening to him with all your wits about you. There is a difficulty in our being able to penetrate through to our own knowledge and experience of what is taking place, because of this kind of diaphragm, this caesura, we can't get past but which makes available impressions not usually available to us when we are fully

conscious and wide awake. That is another reason why I think there is a lot to be said for considering what I have previously called beta- and alpha-elements, but those are not psychological, because I keep them for something I don't know and never will know; I am assuming some kind of physical counterpart. But when it does become conscious, then I think it becomes a somewhat fanciful, theoretical construct – speculative imagination, speculative reasons.

Q: Is the germ of an idea rooted in the patient, in the analyst or in the relationship?

Bion: It is in the relationship, but I think it is very unsatisfactory to speak of it as the transference and countertransference because although they are useful theories they become obstructive. There is something that rapidly comes to exist when there are two people in the room – one of them wanting to be analysed and the other wanting to be an analyst. So the germ of an idea really belongs to both. Of course, it is tempting to say that even in physiological sex this should be true of the germination of a child. If the two people were two minds coming together – not just two physiological objects, male and female, having intercourse – then I think it is quite a different matter. Something different is born, literally and metaphorically, from what is born when it is just a question of two bodies coming together – a penis and a vagina. In the analysis, where there is not usually physical contact, something analogous to that takes place; ideas are born if they are given a chance. I have tried to tell people that no matter how difficult, how awkward, how obstructive your patient happens to be, there is one thing it is as well to realize, because as you realize it, it becomes more and more useful – that the best collaborator you are ever likely to get is not your supervisor, or your teacher, or whoever you go to for a second opinion, but your patient: you are going to get your real cooperation from this person who appears to be so hostile, so negative, so uncooperative. It is easy to be flooded with all this abuse and hostility, so much information that you cannot get beyond it. Conversely, particularly if you are tired, you get a rush of theories to the head; you reach a point where, while it sounds like articulate speech, it is in fact noise, jargon. It is not really fair to expect the patient to be able to unearth the meaning of the floods of psychoanalytic theories to which he is being subjected. It certainly is a collaboration between the two, and there is something fascinating

about the analytic intercourse; between the two of them, they do seem to give birth to an idea, and possibly, if you are used to it, you can turn it into an interpretation or a verbal construction of some sort. Patients get better and better at it until, if the pair are fortunate, the analysis becomes redundant, unnecessary, and they can part and go their own ways.

I haven't had the experience of analysing somebody who has become a composer, but I see no reason why a patient should not find that he is, in fact, capable of being a composer or a painter. Those are things that might come about if the person concerned allows his ideas to germinate in the way they would. Unfortunately it is much more difficult than it sounds; it is extraordinary how much one has an itch to want the patient to say it in his own words. But it may not be his method of communication anyway – he ought to be learning to draw or paint or compose music. That is what makes the actual practice of analysis difficult: you are trying to listen and observe, but you may be observing it in the wrong spot. If you do that, you don't observe where the germ is germinating in the patient because your mind is focused in the wrong direction.

Q: How would you recognize this process of the germination of an idea, the characteristics of it as distinct from the "noise" you are confronted with? Could you describe how you get a sense that that is happening?

Bion: I think it is similar to binocular vision; there is a point of focus at which the vision unites with one's own mind. How that appears from one's own conscious view of the situation is difficult to say. You can begin to feel, "I think I know what he means", and after a time it grows and grows, and you get more and more sure that you are right in thinking that you know what he means, and then you can give your interpretation. That is putting it, as near as I can, into verbal communication when one is quite conscious. Freud talks about being in a state of "relaxed attention". I certainly think that is right, but I think it also implies forgetting these various theories, preconceptions and hopes so that there will be a chance of the point of focus declaring itself.

In your practice you will find yourself under pressure. You say whatever you have to say, and then there is an entirely new situation.

You don't really know what is going on because it *is* an entirely new situation, things will not be the same. It is likely enough that the patient will say, "Why don't you *say* something?" Or if not the patient, the relatives – "Why don't you *do* something?" So you are always under pressure prematurely and precociously to produce your idea. Poor little thing! Pull it up by the roots and have a look at it – it hasn't got a chance. So you have to act as a sort of parent to the idea – protect it and give it a chance to grow in spite of these pressures; you have to be able to tolerate this state of ignorance. Coming towards the week-end break or some other break, you are under pressure to produce some sort of result. I say, "some sort of result", but what you are really hankering after is spectacular cure, something you could really notice, that could really be shown.

Q: How do you distinguish between there being a third person or voice present and other things that come into your mind? How do you sense whether it is a genuine third voice that you *and* the patient can hear?

Bion: I think the sign that it is not right is the sense of anxiety, of being out of step, the feeling that things are not quite coming together. Tolstoy speaks of Prince Andrei saying, "That is sooth, accept it – that is sooth, accept it". There is a certain point, or at least uncertain point, at which one feels that something has clicked. But most of the time you have to tolerate this feeling of being out of phase, or its *not* being right. It is difficult to do because the moments of illumination are extremely rare and very few. I console myself with the thought that after one has seen a patient for, say, five or six years, there may possibly have been three moments of illumination – and three is enough. I am talking about proper illumination, the real thing. There are stacks and stacks of rational explanations, rationally accepted; there is no difficulty about that at all. There are millions of what one might call "correct" interpretations, but the illuminating situations are the ones that really do the work. If the two of them can stand it, they may last long enough for that to take place.

Q: Is the real growth of the mind something that is outside transference and countertransference, where memory and desire are in abeyance and the new idea, illumination, takes place in spite of the change of those?

Bion: They are not always discernible in the direct relationship, but in the course of time they are. That is where there is such a thing as the inheritance of acquired characteristics. For example, nothing will quite undo the fact that Shakespeare existed. Even now very few people can read a Shakespeare play; we are dependent on expert actors to interpret the phrases, and then we can say we have "seen" *Twelfth Night*, or *Julius Caesar*, or *Macbeth*. In the USA, the BBC productions are spoken of very highly indeed; they say the actors are so wonderful. Seeing a production of a Shakespeare play is a stirring experience, but in reading one we ought to be cautious and not get too misled by the fact that we can read – that is not good enough. It is like saying that because we can see black and white marks on paper, we can therefore read music – we can't. So people who aspire to read a Shakespeare play ought to go into a certain amount of training for the purpose, and to have certain minimum conditions in which to read it.

Shakespeare wrote, "The raven himself is hoarse that croaks the fatal entrance of Duncan under my battlements" [*Macbeth*, I.v]. There is only one word that is at all long – battlements. Put the lot together and you get a phrase that does something to you today. Where that comes from, I don't know – I don't know what happens to these things. I am reminded of Milton's reference to Alpheus: "Return Alpheus, the dread voice is past . . ." [*Lycidas*] and so on. There he is using the simile of the river that goes underground and then bobs up again somewhere else. Where it comes up and what effect it may have, goodness knows. A wild phrase of that sort goes through the ages. In a sense we could say, "Well, most people in this country talk English, so it's a perfectly understandable explanation." Yes, I don't want to deny the perfectly simple, straightforward, obvious explanation. What *we* are concerned with are the other explanations – even wild ones – which may be nearer the truth. That would help to explain why this country could never be the same again after it had had a Shakespeare.

The point is much the same with regard to the individual. You are asked, "Who is that fellow?" You can't remember his name, nor can the person you are talking to. Then a bit later, or at another time, you find you know the name perfectly well. Ideas also track their course through the mind and the personality in this way and are very difficult to trace. These ideas that have never been conscious do seem to be floating around and do break through; they come up much

later when the embryo or foetus is actually a sophisticated person. So it is difficult to keep track of even one's own ideas. I am sure that everyone is familiar with the situation in which you are pursuing a certain train of thought and you get derailed, or "derouted", by some upheaval – you "lose your train of thought" because there is an emergence of some obstruction that prevents you from proceeding along the same line.

Q: You made the point about the idea arising between the pair. What about the group – such as the one here?

Bion: There are great advantages in a group. Compared with a narrative story all in a straight line from A to Z, a group is like having the entire alphabet spread out. In short, between the lot of us we ought to be able to mobilize or germinate an idea that would be difficult for any single individual to produce. For that reason there is a lot to be said for universities, institutions like this one, for example, although it is bound to be clumsy because we have to place them geographically – we have to say, "Meet at the Tavistock Centre", and in this way it is dependent on a geographical distribution. But the more widespread the actual members of a group can be, the greater the number of bases for thought there are. This is why I was so impressed when Rickman told me about the private soldier he met at York station who said that the experience at Northfield – the Northfield Experiment when Rickman and I were there – made him realize what a university was. I have often felt that that man, who had had no chance of education after the age of fourteen, knew what a university was, while I very much doubt whether I or many of my contemporaries at Oxford knew that, even when we left. You could get a swimming blue, a rugger blue, a third in classics, a first in Greats, and so on through the list, but all those are irrelevant compared with having learnt what a university is. We had plenty of mental nourishment – so much, indeed, that I think the main point escaped us.

Q: What exactly had he learnt that made him think he knew what a university was?

Bion: I would be tempted to think that he hadn't learnt anything if he thought he had learnt it exactly. One of the difficulties about mathematics is that it gives the illusion of having learnt something "exactly". I think the Intuitionists are right in suggesting that there is

a lot more to be learnt. It is surprising that a man as acute as Keynes, who produced a workable idea about economics that has lasted pretty well up to the present time, should have branched out on writing about the theory of probability. *We* ought to have a great deal more to say about probability than anybody. When we are dealing with speculative reasons and speculative imagination, our only justification is to say, "This is not an exact science, it is not exactly anything." We could say that that introduces a certainty, but in this particular area where there simply is not enough evidence to amount to a fact, we resort to probability – it is *probable* that such-and-such will happen – and we have to be content with that. We have to leave the certainties to other people, and when they have got tired of the certainties they will want to know a bit more about the probabilities.

Q: I am reminded of an experience I had for many years with a patient who is exceedingly accurate. He is very skilled with machines but not with people. Today he surprised me with the following: his wife went to the greengrocer and asked how many pounds of potatoes she should buy for a dinner party of twelve people. The patient was so annoyed with her for asking this question because in his opinion it could never be answered. When he left the room at the end of the session he said, "I don't understand – you say it was fifty minutes, but I'm sure it was only ten."

Bion: We have become used to the idea that time and space can be measured; there are various instruments for doing this, from a watch to the 200-inch telescope on Mount Wilson, to a radio telescope with a very great baseline. These mechanical aids are very useful for our everyday purposes; how much they apply to the realms we are bordering on when we start doing analysis, I don't know. Melanie Klein said to me one day, "Even with the most profound analysis, we can only scratch the surface." She was about right. It may appear to be dogmatic if we try to express ourselves as precisely as possible, but it is not dogmatism we are wanting to express; we are simply trying to use the language with as much exactitude as we can, because it is easier for someone else to understand what is meant if we are fairly constant with the use of words – or, as I put it before, if the individual can learn our vocabulary.

Q: I have been thinking that when an experience is over – such as that of the soldier from Northfield, or that of analysis – we are left

with an idea, an experience to reflect on in tranquillity, free from the "noise" you talk about. Perhaps the times when the analyst is absent during the analysis – week-ends, holidays – are very important too. I would like to hear what you think about that.

Bion: That is the most important thing about it – the actual germination of the idea. But I think this also applies *in* the analysis. People seem to talk frequently as if they thought that the human character or the actual person behaves logically and rationally, but when you look into the matter that really means the person behaves in a way comprehensible to the analyst – which is quite possible if they obey the laws of ordinary social intercourse, the laws of grammar, the laws of articulate speech. But the fact that something is comprehensible to a mere human being is no justification for believing that therefore the universe in which we exist obeys the laws of human grammar, reason or logic. We are, after all, ephemeral creatures living on an insignificant spot of earth that circles (according to the astronomers) round an ordinary star occupying a somewhat peripheral position in a particular nebula. So the idea that the universe obeys the laws in such a way that it becomes comprehensible to us is sheer nonsense; it seems to me to be an expression of omnipotence or omniscience. This is why it is so striking that the astronomers have now discovered black holes in which the ordinary laws of physics and chemistry don't apply; they have discovered two holes – two, to our knowledge, in the entire universe.

Seminar 3

5 July 1977

Q: You referred yesterday to three points of illumination in an analysis of five years. I would like to ask what the analyst was doing in the meantime; I take it that he had to say something. The problem seems to be how to foster and not prevent the moment of illumination arriving.

Bion: The simplest answer is, the analyst is analysing. But, of course, that is simply a general statement. When it comes to the details of it, it is a much more difficult question to answer. I remember being asked a long time ago, "Does the analyst ever do anything except talk?" I said, "Yes, he remains silent." I think there would be a lot to be said for scoring it in the same way that music is scored, where you have "rests" marked. You can even mark the rate at which it is to be played. In fact, each communication requires the appropriate amount of time, otherwise illumination cannot take place anyway.

Take a book that I found extremely illuminating – Matte Blanco's *The Unconscious as Infinite Sets* (1975). It is a tough book to read; in fact, when you first take a look at it you think, "I haven't got time to read this kind of thing", because it is perfectly obvious that either it is an outflowing of more and more theory, or it really has a meaning, in which case one has to spend a great deal of time reading it. To give people an idea of the time required for reading a particular book, it would be helpful to indicate, for example, "120 pages an hour", or, "9 pages an hour".

The illumination, as I have called it, is a very rare event, but it is built up in the time spent beforehand that extends far beyond the areas of any analytic experience. Some people know a good deal about life already, and then they are in a position to understand.

When I went into the army in the First World War, I struggled to learn drill and all that stuff, and I really thought I was a soldier by the time I had been gazetted as an officer. I discovered I didn't know the first thing about it, and the more I saw of action the more obvious it became to me that I knew very little about it indeed – and didn't at the end of it. I was jolly lucky to get out without having got killed through sheer ignorance.

So this whole matter of what goes on in the meantime requires a lot of discussion – much more than is possible here in three days. I hope to add a little more each time I talk to you. But by all means ask the question again; go on asking it. I am reminded of the quotation from Blanchot, told me by André Green: "*La réponse est le malheur de la question*" (which I translated, and he agreed with it, as "The answer is the disease, or misfortune, of the question"). [See also Seminar 1.] In other words, *that* is what kills curiosity. When you have the question answered, that's the end of your curiosity if it is allowed to happen too often. Unfortunately the whole of childhood is taken up by having questions answered – you learn quite early definitions like, "children should be seen and not heard", and are intelligent enough to learn early on to keep your mouth shut because of what you might get put into it if you open it.

Although it is easy to give a kind of mental answer like so many psychoanalytic interpretations, in fact it is much more difficult to say that there really does seem to be a sort of two-way traffic even with regard to thought. So the sort of mental nourishment to which one is subjected from an early age, and which one is very eager to lap up, then builds up a barricade against any sort of illumination whatever – unless, of course, you happen to be one of these pernicious creatures like me. I got a reputation even by the time I was eight as a joke because I was always asking so many questions; I had the answer pushed at me by what happened to the Elephant's Child who asked the crocodile questions [Rudyard Kipling, "The Elephant's Child"].

Q: I am wondering what you would do if an adult patient brought you some paintings rather than trying to use verbal communication to express his feelings.

Bion: I would certainly do my best to look at them and be told anything about them that the patient could possibly tell me. It is a form of communication, and one needs to be able to listen to all that one

is told, even when it happens to be a silent communication – even the "rests" should be listened to. When somebody has drawn a line around his communication, it is very useful to be able to look at it in such a way that one gathers from it what is meant. Let me exaggerate that: suppose you have a chance of looking at Leonardo's sketch of the Virgin Mary and the Infant John. An extremely gifted man is able "to see and tell of things invisible to mortal sight" [Milton, *Paradise Lost*, Bk. III]. This happens over and over again with religious pictures you can see at any time when you go into the National Gallery; the painter has seen something with the utmost vividness and has been able to transform it into a communication with oil, pigment and canvas.

If you were to show a dog a picture of a rabbit, after he had sniffed at it and found he couldn't eat it, he wouldn't be in any way interested. But show a dog a movie of a rabbit, and then he will get really excited – he sees the thing moving and wants to chase it; he translates what he sees into action. I can't show my patients movies; I have to resort to verbal communication, sometimes a verbal counterpart of a pictorial image, as I have just done with regard to this idea of the dog chasing the movie of a rabbit. That is an attempt, verbally, to describe a visual scene; it is typical of the kind of transformation one has to make.

Considering our meeting here: there must be a great many thoughts that we cannot see or that may not be expressed. But as far as all of us are concerned, it is useful if we can imagine that we can keep our minds receptive. I am thinking particularly of these wild ideas and stray thoughts that I consider to be floating around the place in search of a thinker. But, of course, it means that we have to be prepared to be receptive to the thought or idea, whatever form it takes and however wild it may be. I am not advocating what used to be known as "wild analysis"; I hope to come to that point again sometime.

Valéry wrote: it is no good thinking that the poet is somebody who writes a poem in a night of delirium, a drunken stupor, a night of fever; the poet is the cold thinker, almost a mathematician, at the service of an affine dreamer ["*Ce n'est plus le délirant échevelé, celui qui écrit tout un poème dans une nuit de fièvre, c'est un froid savant, presque un algébriste, au service d'un rêveur affiné*" – Paul Ambroise Valéry (1871–1945)]. That is, this person, however cold, however much of the abstract thinker, has to be *at the service of* the dreamer.

Dreams do not obey the theories of Freud or anyone else. There are lots of them; there have been plenty of theories about dreams in the history of the human race. So we should not be too narrow-minded to a point at which we don't even admit the right of the dream to exist – dream in any sense of the word, literally or metaphorically. And if we want to be geometrical, then at least it should be an affine geometry – something that has an affinity with the dream.

When a patient. tells you that he doesn't dream, the really important question is, "Well, what *do* you do then?" He certainly does something, and if he says he slept soundly, it sounds very convincing, doesn't it? But how does he know he slept soundly? Who was awake? Or what was awake? Where did this idea of "sleeping soundly" come from? If it doesn't come from the patient, does it come from the analyst? After all, there are two people in the room in a psychoanalysis. Here we haven't two people; it is like having the whole of one person at all ages and at all times spread out in one room at one time.

I mention this particular point because I know that some people are interested in groups, but I wasn't thinking of that particularly; I was thinking of it as a way of considering a matter that puzzles me very much indeed. Where do these ideas come from when there are two people together in the room? There are plenty of theories about it – transference, countertransference – but I am not at all sure that the very usefulness of those theories hasn't indeed made them redundant, and that the whole subject can be opened up with far wider boundaries than would appear to be the case if one stuck religiously, dogmatically, in a bigoted frame of mind to the actual boundaries that are already laid down – supposedly by Freud, but not all. It is one of these situations that start as the possibility of freeing the mind of its chattels, but very rapidly become a shell, an exoskeleton. And then it is difficult for any sort of development to take place unless room has been left in the skeleton for the further development of the creature inside.

We are perpetually dealing with this difficulty. As we try to express or formulate our findings – as I am trying to do here – so we also excrete a kind of shell around them, a layer of knowledge that we can neither penetrate nor break out of. And very soon we get to the point of thinking, "Well, I don't want somebody to start arguing with me, because they may say something and I shall have to think again." It is much nicer to feel that we are establishing a kind of authority that

can't be questioned and then is an impenetrable shell inside which we lie snugly and simply deteriorate.

Q: I would like to ask a question concerning O. I can understand that we can never know the O but can only become O. What kind of experience is that for the analyst or for the patient at the moment of illumination?

Bion: I find it useful to suppose that there is something I don't know but would like to talk about; so I can represent it by an O, or a zero, or a nought, as a sort of place where something is, but that I am very unlikely ever to get to understanding. I can only go on from such knowledge as I have acquired and such capacity for gathering further knowledge that I have retained. To that extent, at any rate, I think one is a prisoner of the information one's senses bring – sense of touch, sight, hearing and so on. I don't think, though, that it is a good thing to suppose that there is nothing except what is open to our senses – that seems to me to verge on the ridiculous. I cannot imagine supposing that we, as human animals, have really reached the ultimate in knowledge or experience, or even development. It is possible that we have; it is possible that our simian ancestry is much too powerful for us, our simian capacity for learning tricks far exceeds our capacity for acquiring wisdom.

I would like to remind you of a quotation from Ecclesiasticus [38.24]: "Wisdom cometh to the learned man through opportunity for leisure." [Revised Standard (Ecumenical) Edition: "The wisdom of the scribe depends on the opportunity of leisure; and he who has little business may become wise."] I think the version in the New English Bible ["A scholar's wisdom comes of ample leisure; if a man is to be wise he must be relieved of other tasks"] is better; it makes it clearer. The person has to have undergone the discipline required for the acquiring of knowledge; *after* that, there is the possibility of wisdom. But even that is dependent on the opportunity for leisure. So there is everything to be said for making provision for leisure in which these wild ideas, these stupid ideas, these idiotic ideas can have a chance of germination, however much you may be persuaded that the result would be the birth of a monster. Most people are convinced that if they were to allow their minds to be free, they would say something really monstrous. It would be quite wrong to say, "No, no, that's not

possible; it's bound to be something *worse"*, because I don't think so. After all, the Nuremberg Rallies were very remarkable pieces of organization and achievement; there is no question whatsoever about their being highly intelligent people. Whether they were wise or not is another matter. I wonder if there is any other way of finding out except by opposing them – "Take arms against a sea of troubles and by opposing end them" [*Hamlet*, III.i].

In the *Bhagavad Gita* there is a description of a debate between Krishna and Arjuna. Arjuna throws down his arms and says he will not fight; facing the enemy which includes many of his friends, many of the people he loves and admires, he is not going to fight them. Long before I even knew of the existence of the *Bhagavad Gita*, I remember having a debate with three of my friends before battle. The question was, should we or should we not fight? Should we go to our commanding officer and say we were quitting, it was against our consciences? Out of the four of us, I was the only survivor in that action; I never knew a battle in which out of any three people one was not dead at the end of the action. It is extraordinary to think that that was the sort of price that had to be paid if one really had to "take arms". Or to put it another way, when it is a matter of the extremely efficient organization of the Nuremberg Rallies and what seemed to be the incredibly inept organization of the British army, navy and air force, I haven't the slightest doubt of the superiority of the organization of the Nuremberg Rallies or of the Prussian Guard and so on. It seems to me to be a matter of the differentiation between good and evil. I wonder how that matter is ever to be settled unless opposition is taken.

The advantage of talking about a matter of this kind is that it is possible to imagine that one could track an idea through a community in the way that a good doctor can be aware of the ramifications of the lymphatic system in order to detect the spread of tubercular disease. In the same way it might be possible to track the course of an idea in a group to find out how thoughts or ideas spread through a community.

With regard to these wild ideas – if one dares to harbour them – after a time something happens to them and they can emerge in such a way that you can give them a name like "speculative imagination", or "speculative reason"; you can put a tag on the thing. Or

you can say that you feel "anxious" or "frightened" or "terrified" – a few simple words used as labels to tag on to a particular sensation or idea that you get.

Then again, you can comprehend it pictorially: "Return Alpheus, the dread voice is past that shrunk thy streams. . . ." [See Seminar 2.] Milton is describing the way in which the river flows underground and then bobs up again somewhere else; it becomes famous as being the same river that re-appears in extraordinarily different places.

Unfortunately we are educated so that we think we have read or been taught poems like "Lycidas". But once we think that, there is no chance of observing the astonishing performance of that Cambridge undergraduate who was able to put these thoughts and ideas that had emerged in him into such verbal form that we can even quote it now over three hundred years later. When you see today's patient tomorrow, who are you seeing? What are you in contact with? When or where or how was it born?

Q: Would you be prepared to say why a result of speculative reasoning or imagining sometimes seems to be ambiguous and sometimes confused?

Bion: It depends partly on the answer and partly on who or what hears it. There is always this problem of the formulation of the statement, however it is done – whether by a painting or a piece of music or by articulate speech. There is also the problem of the receptor and whether that receptor is sufficiently mature to be able to tolerate information that is brought. For example, "*Les espaces infinis m'effraie*" [Pascal, *Pensées*, iii.206: "*Le silence éternel de ces espaces infinis m'effraie*"]. That statement very clearly expressed the terrifying nature of being aware of astronomical space. Because of the limitations of our ability to see, we don't much mind about astronomical space at the present time. We *do* get a bit sensitive and restive if the space to which attention is drawn happens to be the space that we ourselves occupy; we are already in possession of it, and we don't want to be disturbed by the invasion of forces or thoughts from somewhere else – either the past, the future or the present. There is always this tendency to build up a defensive mechanism so that our own system of architectonics will remain intact and cannot be invaded. So a shell develops like the dinosaur's armour that becomes so heavy it can't walk. Its

armour appears to be a successful response against the stegosaurus, but between the two of them they end up by being extinct – unless, of course, we still have our mental dinosaurs.

To return to the problem of where ideas get to as they track their way, like Alpheus, unseen, unheard, unobserved: are we not sufficiently trained? Or haven't we the skill to invent a counterpart of the electron microscope and have to fall back on such senses and commonsense as we have because there is no apparatus? Even when we do have the apparatus that could make us more perceptive, once again we wrap the apparatus around ourselves. So when a patient goes for a consultation, the doctor says, "Right – X-ray please, electrocardiogram, blood count" and so forth, and off to the path lab they go. So we get to a stage in which the "answer" rests in the hands of a computer: shove in the test results and out pops the diagnosis. If that goes on long enough, with a bit of luck we shall not need minds at all; there will be no more trouble. "*La réponse est le malheur de la question*" – that's what will kill curiosity in the end. It is so harassing to hear, "Yes, I know. Yes, I know. Yes, I know" over and over and over again. It is a nervous tic, like "I mean to say" or "You know". It's not the unconscious; it's a sort of modern version of the unconscious, a kind of way of doing without an unconscious by having such an apparatus of mental bricks and mortar that you can build up this wall all the time – "Yes, I know", "You know", "I mean to say". You can go on like that for ever because you just don't have to think, And if you are the analyst trying to say something to the patient, you've got your work cut out.

Widening the view a bit: "The last man through bolt the Menin Gate" – there was no Menin Gate. Or, "Build the wall up with our English dead" – another way of putting it. So you can keep a good supply of dead thoughts and dead phrases for blocking the holes, for preserving one's small stock of knowledge undisturbed.

With regard to the work of the astronomers, suppose we are being affected now by waves set up by the explosion of the Crab Nebula in 1054. If that sort of thing is said, one day astronomers will become extremely unpopular people because they will upset and frighten us. At present it is only doctors, psychoanalysts and suchlike who upset people by saying, "I think you need an operation", or "I think you might try analysis".

Q: I am increasingly aware that although you invited us to entertain wild thoughts, the response of people in the room has been very tame in the way that questions are phrased.

Bion: It is very difficult to give expression to the wild idea. If people can possibly bear to have a wild idea and allow it to germinate, then they might be able to put it into a form that made it more communicable. In *Finnegan's Wake* Joyce says that you would have to spend your life reading it to acquire the language or the capacity to understand it. I don't think anybody is likely to do that. But then you get this curious effect: perhaps in another fifty years people will be able to read *Finnegan's Wake*; what has happened to the wild ideas that are triggered but not expressed, we cannot tell. But they *are* communicated and you do get this extraordinary effect that, if it were purely physical, could be expressed by the laws of Mendelian inheritance. But nobody that I know of has expressed the laws of the inheritance of acquired knowledge, and yet I think it takes place.

The advantage of the point you have mentioned is that in a group of this kind, maybe we could see the sort of thing that you describe, but also see the way in which an idea tracks through the community, and from that regard it as a sort of model that gives us some idea of how an idea tracks through the mind of the individual, using this very small community which is the totality of the thoughts, ideas and feelings that appear to be bounded by the physical integument of the body.

[*No more of this seminar recorded; approximately one hour missing.*]

Seminar 4

3 July 1978

Matti Harris: I don't think I need to introduce Doctor Bion to most of you here. We are immensely privileged and delighted that he is able to continue his series of talks he gives around this time every year, giving us the opportunity to share his on-going thinking and development – in so far as we are able. I think he would like me to emphasize again that he is utterly willing, and even eager, to be interrupted at any moment by any questions however "wild" they may be (as some people felt theirs were last time). Those of you who have had this experience will know that you will always get an unexpected answer which may seem extremely enigmatic, but afterwards may be very illuminating – and sometimes incredibly obvious.

Bion: The problem that seems to me to be extremely important and, I think, more important every day, is one of observation. I get so sick and tired of hearing about the various different schools of psychoanalysis and their great superiority to the other one – whichever it is. The possibility of arguing about their various merits is simply endless – as long as you don't anchor any of it to facts. I don't know of any scientific work that is not based on observation; it is a great comfort, because if you can base it on observation, then you have something to go on that is as near to fact as you are likely to get in this extraordinary subject.

If an individual finds that he cannot see, then the chances are that he will use a stick that he waves about, prods the ground, and seems to rely upon it to give him information. He learns how to use it and appears to be able to diagnose or interpret what he gets from striking other objects or feeling that the ground is soft or sandy.

What kind of stick or instrument do we use when we are concerned with what is supposed to be the human mind in order to supply us with facts we might be able to interpret? Psychoanalysis is alleged to be one of them. Of course I went through the considerable training courses both in the old Tavistock and the Institute of Psychoanalysis, learning more and more theories I understood one needed to know. But long after I had completed my training course and had begun to recover from that traumatic experience, I really thought I began to get an impression of what it was all about. I don't think I am yet satisfied as to what that impression was or how I gathered it – that is one reason why I would like to continue debating the matter here. You may be able to throw some light on the subject of what it is that we are observing.

Q: You used the word "mind" just now. In some of your books you prefer to use "personality". I am very interested in that distinction.

Bion: It isn't really a distinction; it is due to the fact that I don't know what to call the "thing". Sometimes I call it the "personality", sometimes the "character". Freud talked about an "ego", an "id", a "superego"; we hear of "soul", "supersoul", "spirit". The French have a word, "*sortilège*"; I don't know how to translate it, but it comes very close to it. "How to translate it?" That is the trouble. I have no doubt about its existence, but I cannot think of a suitable term, even falling back on such English as I know. I'm glad you asked the question because it goes straight to the root of the matter.

How are we to get anywhere whatever in the direction of what has so far been called a "scientific view"? Freud seemed to think that he was making a scientific approach to this question of human personality. There is a great build-up of psychoanalytic literature, and a great build-up of argumentation about these various theories. But the theories continue to be elaborated, and there continue to be people who think they have had an experience they would like to communicate. Melanie Klein was one of them; Abraham another; Jung, Stekel, and many more. But suppose someone thought that music might be a way of exploring – that is one human activity that plays a great part; philosophy is another; mathematics another.

I had occasion not so long ago to talk to some rather distressed parents and a very distressed teacher; the child in question could not learn mathematics. There didn't seem to be much the matter with the

child – quite intelligent, but an absolute b.f. when it came to mathematics. Very puzzling: "2 and 2 makes 4"; he could learn that by heart one day but had forgotten it the next. I asked the teacher, "You must be able to hear what he says about this." "Yes." "So, can you tell me what he says 2 and 2 *does* make? Obviously it doesn't make 4 – that is something he has picked up from you and his school. But even so, he cannot grasp what it means, and forgets it." It turned out that the teacher didn't know what 2 and 2 meant to the child, so I said, "You had better listen to this boy doing mathematics and find out what *his* mathematics are, and what 2 and 2 does add up to." Then one could fall back on a basic fund of knowledge; I have forgotten what it was like to be asked what 2 and 2 make, or to divide 10 by 5, and so on, but this small boy (from what they told me, obviously intelligent) made extremely acute remarks. So there couldn't be anything wrong with his senses – what he hears, what he sees. The information his senses bring him doesn't seem to have anything wrong with it, any more than one could say that if a blind man trips up and falls over, there is something wrong with his stick.

Some people have difficulty in learning how to play the piano. Someone told me that he simply couldn't make head or tail of it; he did his exercises and so forth, but didn't really get anywhere. But later, when he had children of his own, he found that thanks to the piano exercises he was a first-rate wrist-wrestler. So the muscular development had paid off; you could at last see a very good reason for those early years of music lessons.

Not long after this the very same person began to feel rather pleased he had learnt the piano because he got pleasure out of the musical sounds he was able to make. So there was some kind of expansion, development, going on in his mind/character/personality; this curious facility for playing the piano was conveying something to him that had now begun to have a meaning.

It is something like that I feel about this matter of psychoanalysis and characters and personalities – even groups of people. For example, take us here: why or how has such a diverse mass of people come together at the same time and in the same place? Of course, that can be very easily explained – so easily that it is completely fallacious, just one of these bits of knowledge that are a frightful nuisance. Indeed, I feel that most people reach an age where they have so much knowledge that they can't penetrate through to the wisdom – it's a new kind

of forest that you can't see for the trees: you can't see the wisdom for the knowledge. It is peculiarly harassing to listen to someone like that; it comes over in this way: "yes, I know", "yes, I know", "yes, I mean to say", "but you know . . .", "what I mean is . . .", and so on ad infinitum. Rather more harassing, because it appears to be slightly more meaningful, is the command of masses of psychoanalytic theory. The noise that those theories make is so great that you can hardly hear yourself think. I find it is then useful to be able to shut off one's awareness of what is going on so as to cut down the turmoil enough for some relevant fact to get through, something we could call "evidence" on which to base our judgement.

The great advantage of individual analysis is that you have the collaboration, if you are lucky, of the one person who really knows – the patient. I think it is fairly easy to see that it is likely that the patient knows what he feels, and knows what it feels like to have a particular feeling. For example, he is feeling "terrible", or "anxious". I don't find that very illuminating, but I feel the impulse to take it seriously because it seems to me that it is the sort of verbal formulation of what another person might say – he has a pain in his hand and "it hurts". If you are carrying out a physical examination, you say, "Where is this pain?" Or the patient shows you the place in his hand where it hurts, and you can continue your examination from there.

The kind of people I am talking about don't tell you "it hurts"; they say they are anxious or frightened. I am convinced that that is simply an approximation, an attempt to verbalize something not yet verbalized; that patient is suffering from pain.

Falling back on ordinary speech, as one has to, I have to say, "mental pain". I think it is a rotten expression, but it's the best I can do. It may get a bit clearer later on as to why I don't think it is good enough.

If the person in question is a painter, then he employs various shades of colour that are much more subtle. In fact, what he is doing is really exploiting light – and that is very near to becoming something that can be scientifically expressed in angstrom units and so forth. We are not so lucky as to have anything so precise – we have to put up with words like "anxious", "terrible", "frightened" or sometimes, "I had a terrible night last night. As a matter of fact we had a very good evening indeed." This last example is most effective because you are invited to pay no attention whatsoever to the fact that the patient said

he had a terrible feeling. But when the patient enters the consulting-room, I regard myself as fortunate because he is so cooperative as to have taken the trouble to get there and present himself, and I am lucky enough to have a chance to observe this person who is not me.

The communication, whether it is what I can see or hear, presents me with what I now think of as "mental debris" – all this stuff that has accumulated between the time of birth and that particular morning; the stuff learnt in school, from parents, from the senses. I am not sure about this matter of when we were "born": I have no idea when the optic and auditory pits become functional; I have never heard anyone offer suggestions about that, but clearly, at some stage, there is a development taking place that makes available to the embryo or foetus what one day we could call "sensations", feelings, thoughts, ideas. Whether it is pressure of the amniotic fluid on the optic pits, or waves that are produced, I don't know. But I can see that in this sense the debris I am talking about can be a very considerable collection.

I can watch the patient, see him lie right on the edge of the couch, and wonder why on earth he does that. Why not lie comfortably in the middle of it? Why doesn't he say anything? Or why does he say, "yes, I know, yes, I know", ad infinitum? Why does he say he has no imagination, has dreams, or has no dreams? – and so on and on . . . I have to observe *all* of it just on the off-chance that somewhere amongst all this debris there is a scrap of information that is important.

I'm sorry not to be more precise than that – all I can say is that I still feel the need to be aware of this debris, not to allow myself to miss the chance of getting information in the hope that in my sieve-like mind I will catch up here and there with a piece of knowledge that is quite useful. Doing this sort of work fairly continuously and for a long time, perhaps one gets a bit more sensitive to these bits of significant debris.

I find the prospect of the patient coming to me for ten years, fifteen years, twenty years, somewhat unappealing – especially when he seems to be perfectly satisfied with the experience and the life he is leading but that appear to me to be disastrous. And yet, so much of medical practice – not just psychoanalytic but all the practice intended to be helpful to the human being – seems to me to lack discrimination, as if we had no way of being selective and don't know what to select. Unfortunately I think it is true. I have a better idea now, on the whole,

of what I am likely to select, and I have a pretty good idea, too, since that is the case, that I long to be able to say, "Thus far and no further: what I don't know isn't knowledge", simply getting to a point where my defences, my resistance to any further information, will protect me from having to start thinking all over again. I try to resist that; one way is by regarding the patient I see at that session as an entirely new one. That is not so very wild, because time has passed and people get older; the patient you see today is *not* the same as the one you saw yesterday; nor is the one who started speaking a sentence still the same as the one who finishes it. It is a rather painful business; I find it very hard to resist falling back on what I already know about the patient, resisting having to think afresh, having to tackle the situation as if it is an entirely new one to which I have to bring a fresh mind.

To sum up: we are presented with the debris, the vestiges of what was once a patient and what still could be analogous to blowing on the dying embers of a fire so that some spark communicates itself to others; the fire is built up again, although it appeared to be nothing but dead ash. Can we look at all this debris and detect in it some little spark of life?

[*Tape recorder sounds faulty – section missing*]

Bion: Why does Newton engage on what I gather is a mathematical activity and start talking about life? And why does he similarly seem to encroach on what would appear to be a theological investigation? Why does Descartes find himself defending a theological position? The explanation he gives is quite simple: he does not like what happened to Galileo, and he doesn't want to get into the same difficulty. But his argument is not at all a good defence of that statement – in fact, it isn't a defence at all. It is quite clear that he is not intimidated by what has happened to Galileo. Over and over again there is this curious business of an inquiry, an investigation, followed by the link-up with what appears to be a theological theory or idea.

Freud talks about the future of an illusion [1927c; see *Cogitations*, Volume XI, pp. 345, 348, 349]. I think it is quite an interesting speculation, but I would feel a bit happier if I knew which illusion, what future it is that one is investigating. Unfortunately, nowadays the collection of debris is very much increased by that of psychoanalysis. I don't think we hear quite so much about father-figures, but quite enough to get on with. Somewhere hidden amongst all this debris

you can get a glimpse of actual suffering. It is rather difficult for analysts because we get almost hardened to human suffering – like doctors or surgeons who become so used to hearing about anxiety and so forth that they forget that it hurts. So we have to beware thinking that we are hearing about the real thing when what we are really hearing is the remnant of psychoanalysis. We cannot discard it on the grounds that it is simply a remnant (for the reasons I have already given). Therefore, we have to go through it all, whatever we are feeling like, on the off-chance that buried somewhere in this stuff is something that matters. And that brings me to the question I asked at the beginning – namely, what is this personality, mind or character?

If we could narrow it down and say what it is, then we might know what we are investigating and why we spend so much time and effort on this occupation. Of course, there are plenty of reasons that can be very easily arrived at, but I still feel there is a *real* reason, although there is a good deal of evidence to suggest that we tend to follow . . . [*break in recording*] under the impression that it is real illumination – cure, a good time coming, heaven, hell and so forth. So the seductive paths – what Shakespeare calls "the primrose way [that leads] to the everlasting bonfire" [*Macbeth*, III.iii] – are plenty, very effective and perpetually seducing us, or urging us in the wrong direction. The idea of "right direction" is curiously robust: the Chinese call it the Tao. Nearly all races of people at one time or another have stated that there is a Way, a correct path. So that is also worth further investigation when you get a view of it, perhaps in a patient who actually comes to you showing signs of thinking that there is some dread path from which he or she has strayed. Whether we can get this same idea from a group of people, or even a nation, I don't know. At the present time, people wonder why this country is in such difficulties. It seems to me that there are various, somewhat obvious explanations, such as if a country fights two Great Wars in succession, and is the only country to fight throughout both, then it is sure to have to pay for it in some way or other afterwards. [See also Seminar 8.] It is typical of the kind of question that plagues us; in fact, curiosity itself is a bit of a nuisance because it doesn't let us rest; it always leads to wanting to know more about something of which we know nothing.

Q: [*inaudible*]

Bion: When we are awake I don't think we really know much about the state of mind in which we are when asleep. As a psychoanalyst I have been taught a good deal about the interpretation of dreams. The only thing I am not quite clear about is, what was the dream? Because when I am told that the patient has had a dream, it is told me by a person who is in an "awake" state of mind [see also Seminar 3]. I sometimes ask patients, "Where were you last night? What did you see? Where did you go?" I don't accept the answer that they didn't go anywhere, they simply went to bed and went to sleep. But I still think they went somewhere and saw something. It is possible that if the patient says he had a dream, it is a sort of vestige that is sufficiently robust still to be apparently available when he is awake. I find it very difficult to believe that the story he tells me is the current version of where he went and what he saw when he was in that other state of mind, partly because I have felt increasingly that there are occasions on which there is evidence of this state of mind when he was asleep. For example, the patient who lies on the extreme edge of the couch tells me that he dreamt he was sitting on the mantelpiece – some narrow ledge on which it would be impossible to sit. So there are these curious survivals into a state of mind when the person is awake, of events that occurred when he was asleep. At other times the patient appears to be awake and fully aware of much the same kind of circumstances as those of which I am aware in the consulting-room. As he goes on talking – it may be for as much as a month or so – I begin to feel there is a pattern about his behaviour that shows he is not experiencing the kind of events that I am experiencing. There are lots of words like "hallucinations", "delusions" and so on; they are very inadequate formulations because the experience I appear to be witnessing is much more subtle – so much so, indeed, that I couldn't very well give you a description of it.

I have had occasion to say to a patient, "You say that your paper on so-and-so has been rejected. I gather from what you say that it is a good paper. Why are you bothering about it being rejected? Surely, if it is a good description of an actual experience, people would be interested to hear of it." Some descriptions of the way that human beings behave seem to gather quite a lot of interest. If I were offered the choice of seeing how Shakespeare thought that human beings

behave, or the chance of hearing a psychoanalyst's description of how a human being behaves, I think I would get a much better impression from Shakespeare. What he says reminds me of people; it makes me think that the sort of person he is talking about could possibly behave just like that. But most scientific papers don't throw me in that way; I don't look forward with a vast and vivid interest to the next edition of a learned journal, because I don't think it is going to remind me at all of how human beings behave or, indeed, of how I or other people I see for myself behave.

There is something about a patient coming into your consulting-room that makes you feel that behaviour is *about* something. The patient can say he doesn't want to come – he has come because he was sent. When he says he has just been sent, you can feel the untruth of that statement. It is not only the evidence of his actual physical, bodily presence – there is something else about it. Related to it is an experience you can have when the patient is said to be very idealistic, idealizes the analyst, and it is perfectly obvious that he does. But what is "perfectly obvious" is of no importance; what is important is what is behind that. If the patient finds that the universe he lives in isn't good enough and he has imaginatively to construct a better one, then what matters is *why* he has to construct a better one. Is it just sheer cussedness on his part? Or is there actually something wrong with the universe that we occupy? These are profound questions that have bothered the human race throughout history. When you get a little bit of history coming into your consulting-room trying to idealize you or some other person or analyst, the important thing about that is the force or drive leading to that idealization. The fact that it surfaces in the form of idealization may be a characteristic, but what really matters is "it" – the "reality". There is something about this part of the experience that could be called "real" – it produces a different feeling from "unreal".

I don't want to appear to be criticizing or running down my colleagues, but I have recently become more and more convinced that psychiatrists and psychoanalysts don't believe in mental suffering, and they don't believe in any treatment of it. In fact, they are living in a very precarious frame of mind, trying hard to believe in psychoanalysis – an awful effort and a continuous strain. Fundamentally they never get to the point of feeling that the person who comes to the

consulting-room is actually suffering and that there is an approach to it that is on the right lines. Even psychoanalysis may be close enough to be on the right track, to be worth pursuing further. But not, "yes, I know".

It is a very curious thing indeed for an analyst with many years' experience to discover that his patient actually suffers pain. It opens up the questions: What are the dimensions of mental pain? Where does it hurt? Is it internal or external? Internal object or external object? All this is learnt so easily by intelligent people; a technical facility, very easily acquired, tends to produce a barrier against the real thing.

The experience of reality can be very unpleasant because it always carries with it the recognition of one's ignorance. You pick up a little bit of knowledge and wonder why you couldn't see it before, and what you are seeing now. So anything that you learn immediately makes you aware of the enormous area of the unknown and the incapacity to learn it.

Deflection from the path of learning is very seductive. You are likely to be misled because you are so pleased to be misled, with the result that even if you have a satisfactory experience you can doubt its validity. You can be pretty sure in any case that you would reach some satisfactory conclusion – the song the sirens sing is still audible to most of us; we are always invited to go off on some side issue as THE solution of all our troubles.

We are used to the difficulty of thinking clearly – a very feeble ability. Anybody who has the wit to arouse strong feelings can destroy your capacity to think clearly: if a patient threatens you with physical violence – either to himself or to you – it is very difficult to go on thinking clearly while going through that experience. The classical exaggeration of this is in war, where the fear for your actual existence can be so powerfully aroused that you cannot think clearly. In this respect a *real* soldier is different from an amateur, somebody who has not had a professional training or is not engaged in what is his natural profession. There is a great difference between that kind of person and one who is simply a temporary soldier.

Q: [*inaudible*]

Bion: I have great sympathy with the philosopher's aim to think clearly, and with his objection to anything that might endanger that

capacity. But I also have a great respect for facts – even those I don't know.

With regard to objections to psychoanalysis or Mrs Klein's theories and so forth, I don't mind very much about people who don't believe in those theories. For one thing, I don't expect to hear them expressed adequately. Any formulation of a theory is really a crystallization of it; it doesn't leave room for mental growth or development – but it also provokes it.

An analyst should leave room for the growth of ideas that are being germinated in the analytic experience, even though the germ of an idea is going to displace him and his theories. I don't take the objections very seriously because Kleinian theories bear a great resemblance to sin: everybody is against them, but everybody practises them in secret. The secret of practice has a way of going on spreading, and if it is capable of development, so much the better as far as we are concerned.

I do sometimes wonder if the human race has reached the end of the road: its capacity for thinking clearly is just not adequate for the job that has to be done. If the astronomers are approximately correct in thinking they have discovered these black holes, for example, in which the laws (as we call them) of physics and chemistry may not be applicable, then the question is whether we are capable of finding any way of thinking or dealing with those situations.

Q: [*inaudible*] . . . the question of whether psychoanalysis can be killed, or a thought, once it has found a thinker, can be annihilated either in the individual or in the group.

Bion: I think the individual can be annihilated; I don't see any particular reason for excluding the possibility that the human race could blow itself off the face of the earth, anyway. Technical ability has now become good enough to be able to produce really effective bombs. But I don't see how the truth (whatever it is) is going to be annihilated; I don't think it much matters whether we can grasp the truth or not. The laws of chemistry etcetera seem to me to be not of much higher status than the laws of grammar or English speech – very useful for purposes of verbal communication – but to suppose that the universe itself obeys the laws of English grammar seems to be entirely futile. And yet we very often behave as if there really were these laws that are something more than symptoms of our logical capacity.

The position of the formalist mathematicians, the logicians, is challenged by the Intuitionists – although what they say is very difficult for most of us to understand at all. But although we cannot understand it, or they may be wrong, they can be right in one respect – namely, that a purely logical construction does not go far enough, nor does an ability to *make* logical constructions, because the truth that has to be grasped can be far beyond our capacity.

However, the disposal of the human race is not really a matter of much concern; what does concern us is the extent to which we can live what remains of our capacity to exist in a manner that might be worth living. The capacity to think has so very few prizes to offer, in contrast to material possessions, that it is hard to get people to realize that there might be something to be said for thinking as being both enjoyable and useful.

Seminar 5

4 July 1978

[*Only a limited part of this seminar was recorded.*]

Bion: That mobilization is something outside the group, the mobilization of the people who concentrate on the body, trying to keep the mind in its proper place. The development of the mind has been a frightful nuisance and has caused an awful lot of trouble. I think we are still frightened of it. That is why we [*inaudible*] . . . to what I call "wild thoughts", and anyone who will give a home to those thoughts flying around looking for a lodging, looking for a thinker to think them.

Q: [*inaudible*] . . . brought together two different concepts of yours – one, the beta-element, and the other the protomental apparatus. I don't quite see how they wed with one another [*inaudible*] . . . only for evacuation, and now you seem to be talking about them as manifesting themselves in somatic phenomena, habits and things of that sort.

Bion: I invented the term with the idea that it could be vacant, a space "to let", as it were, that could be borrowed for purposes of clarifying something or another. But there are things that do seem to me to suggest this combination between the body and the mind. Why do the old anatomists call part of the brain the "rhinencephalon"? Why a nose brain? Why is a patient always complaining of a rhinitis? Psychosomatic? Soma-psychotic? Take your choice. "Pure and eloquent blood spoke in her cheekes, and so distinctly wrought, that one might almost say, her body thought" [Donne, "The Second Anniversary"].

Some of the later developments of Confucius or his followers seem to suggest a sort of physical approach to what we regard as

mental symptoms, mental diseases, and the suggestion seems to be of an athletic form of activity, as if they thought an approach had been made to these very primitive levels of mind via the body. When you think of this tendency, I think you will find with your own patients that sooner or later they have taken up dancing or gymnastics or eurythmics because of this need and urge to sweep athletic capacity into something that is so heavily concentrated in the direction of thought like psychoanalysis. Of course, it is very often done as a substitute for psychoanalysis, but not necessarily so – it may be a useful auxiliary.

Q: Bearing in mind the example you gave about the boy who could learn that 2 and 2 make 4 without understanding it [see Seminar 4], and the theoretical knowledge one can amass with internalizing it, converting it into wisdom, do you think it is inevitable that we have to go through a process of adding it on before we can reject the debris that isn't required? Is there any way round that? Do you have to amass it all before you can reject it and clear yourself?

Bion: I haven't found any other way. Although I have plenty of reasons to be aware of the defects of the analytic approach, I can't think of anything better. The defects of psychoanalysis are bound to be painfully obvious both to the analyst and the analysand if you are at all sensitive to what is going on, but I don't know of any way of avoiding that. There is even danger in the educational system of supposing there is a way in which pain can be avoided. I don't think there is any way of teaching people mathematics or the piano or violin in such a way that the pupil does not think, "Right – when I've learnt this damn thing I will never do it again – I will never voluntarily submit myself to a musical or mathematical experience." That's hopeless; I would like the educational procedure to be of such a kind that a person might feel that he had learnt the violin because he would like to go on learning it. Otherwise, you get a position where the extremely gifted musician has a breakdown and concentrates on teaching the instrument rather than concert performances, fundamentally because of the rebellion against his own capacity – the better player he is, the more hostile he feels to a capacity that makes him spend all his life as a musician – or even a teacher. So I think there is everything to be said for not exaggerating what is in any case a painful procedure; learning anything new seems to be very painful.

Q: Could you say a bit more about people's rebellion against their capacities, talents, feeling that they become enslaved . . .

Bion: I think it happens over things that are quite fundamental. For example, a child who is potentially maternal or paternal can be very alive to the fact that its mother or father is not treating a younger sibling wisely, but is quite unable to do better; if it is left in charge of the younger child, it does the job very badly. A person like that has to put up with many years of frustration before he or she has the chance to be a parent, and by that time they can hate anything whatever to do with what we nowadays call "sex", because they regard sex as having landed them in this trouble when they have sons and daughters. That seems to be against the very capacity to be maternal or paternal; it militates against the solution of the problem and contributes to the difficulty that arises in the course of any attempt to harmonize one's personality – how to get all the various impulses to live in peaceful harmony within oneself. The job of looking after that internal family is too much for the child. That is one reason why I think child analysis can be so extremely creative and can release these capacities in such a way that they can be harmonized.

Q: What is it that makes it possible to differentiate between "me" and "not-me" experiences?

Bion: I don't know – and I am not at all satisfied with the attempt to talk about a soul, a personality, a supersoul, an id, an ego, a superego and so on. Those terms mean very, very little to me, and I find little that corresponds to them in my analytic experience. In the Society of Jesus, there is this idea of the "arbitrium": it is something that decides, has an executive function and represents the community of one's own interests or one's conflicting interests.

Cancer is one of these diseases that have a great appeal because of this quality of undifferentiated, undisciplined greed; there is only one way in which they agree, and that is to devour the body on which they are parasitic. But there are plenty of cancers that are not physical and that will in time become easier to detect in the sort of mind that is extremely skilful at mobilizing all its abilities concerned with "taking", in contrast to the sort of love that is "giving". The "taking" person will metaphorically bleed a group of all its life; that group will gradually succumb because of the presence of that person who takes the very life out of it.

Seminar 6

5 July 1978

Bion: The difficulty in practice is this matter of scrutinizing what I have called conversationally – I would hate it to become a technical term – the debris. Perhaps what I mean by that may become clearer as I go on talking about it.

When the analysand comes into the room, is it possible to see the total situation, as it were, having denuded oneself as far as possible of one's preconceptions so that there is a chance of being aware of any facts that need to be observed? Although I am concerned fundamentally with talking to the patient, I am also concerned with the fact that he has a body and a mind. That division – body and mind – is convenient for conversational purposes, but it is a distortion of the facts because he is not "a body and a mind": I find it useful to think of a person as "your Self". But I would also like to make it clearer what I mean by "your Self" when I am wanting to stress either the somatic or the mental qualities.

Take this instance of the patient who appears to be perfectly fit and healthy, comes in, gets onto the couch and lies down. After a time you begin to notice that he hardly seems to disturb the covers on the couch; when he gets up and goes out, you don't have to smooth the covers – there has been hardly any movement. As you go on observing, a pattern begins to emerge (as Freud put it, quoting Charcot) and you notice that the patient lies precisely in exactly the same place. There is nothing remarkable about that, but when he lies in exactly the same place day after day, week after week, year after year, then I think you begin to be suspicious that he might just as well be lying on the edge of a precipice; from the amount of movement that he makes, he is lying in exactly the way that he might appear physically if he was in a cataleptic state.

It takes quite a long time before you see a point like that; it builds up over a period, and then you gradually see that there is something peculiar about it. The next thing you notice is that he says he has no dreams. In response to the question, "Where were you last night and what did you see?" he says, "You mean I had a dream?" Then what comes out is remarkably like a fact that you are acquainted with. Then you begin to think: this man is lying somewhere between what I am used to thinking of as the conscious and the unconscious; I think he is right – he doesn't dream. He is also right when he says he has no imagination. Whether he is telling me facts or whether he is telling me dreams – so-called – they are the same thing, a kind of mental counterpart of a cataleptic state. No wonder he makes no progress at all; the interpretations I give are based on ideas that some elements are conscious and some unconscious.

I had much the same sort of experience with another patient who was totally unfamiliar with, and apparently had no experience of, frustration – never been conscious of it, never been aware of it and therefore had no experience of it in the analytic sessions, never by any chance telling me what I might regard as a fact. I have no material to interpret, so I have to make a shift. I have to find a vertex from which these things will look different. So I begin to wonder what is wrong with this story: day after day this sort of behaviour, and apparently no progress at all and no objection to making no progress. It occurs to me that many of the interpretations I give could come over to the patient as being entirely obvious, as if I were simply repeating back to the patient what he has told me; the patient says, "Yesterday I went out and did some shopping", and I say, "Yes, yesterday you went out and did some shopping." So the question is, in what way is this story queer?

From that point of view, I can gradually shift onto a vertex from which it becomes clearer what the shape of this thing is. For example (this is something reported to me, not my experience), a patient had come for analysis for many years and then was admitted to hospital with an incurable cancer in the terminal stages. He asked to see the analyst and then blasted him for having completely failed to realize the seriousness of the condition he had always been talking about. Why did he want to see the analyst? Simply to have a chance of getting off his chest how much he hated the analysis, how much he hated the analyst and what a shocking piece of work he had done?

There is something very queer about this story. If it is true – and I don't doubt it – that this patient was in the terminal stages, you would think he would be concerned about how to spend such remaining hours or days, possibly weeks, of life in a way that was worth while. Why, then, does he actually ask to see the analyst simply to blast him in that way?

I suggested that the analyst should draw attention to this fact, because it seemed to me that this patient had never really dared to express the anger and frustration he felt; the nearest he had got to achieving that sense of freedom was with the analyst. It was no good expressing it to any of the hospital staff because they were concerned with telling the patient reassuring stories about the state of affairs and suggesting various forms of chemotherapy and so forth. I think this patient was longing for a chance of telling the analyst what he really felt and having the analyst speak the truth back again. The patient might have liked to hear just a faint dose of truth for once in a way before he died – a kind of last fling. That is what I mean by changing the vertex so as to see what was wrong with that story.

The analyst tried it out and was surprised and relieved to find that the patient began to talk of other things, including his dislike of the apparatus surrounding him – the apparatus that was intended to preserve his life but that went a very long way to making him extremely uncomfortable for such hours of life as he had left, and from a mental point of view was completely unconvincing. Nobody wants to be turned into a sort of nerve/muscle preparation to be kept alive simply in order to see the muscles twitch – and that is very nearly what was happening. The philosophical view behind it is that people need to have their lives preserved by whatever artificial means are available regardless of whether or not they want to go on living.

The patient who didn't tell me any facts at all didn't seem to lead any life whatever but was always telling me about somebody else and never experiencing frustration; he didn't have to because as the analyst I *did* feel frustrated. The explanation is so obvious that one feels a bit suspicious about it. I think it is a situation in which the patient is projecting part of himself into me so that I experience frustration but he does not. Nobody knows where that patient is – not even the patient. From that point of view, one could locate the frustration in the consulting-room if it was just frustration felt by oneself. But the

location of the frustration was, in fact, faulty. Falling into it, having that experience and being the person who is made in various ways to feel frustrated while the patient is free of it is indeed a mysterious situation. One feels that there should really be some facts to support it – what are ordinarily called facts – but what *I* ordinarily call facts weren't there.

I know of no way of investigating this except analysis and having this kind of experience in which one can locate the presenting symptom. In this instance, it was my frustration. After I noticed this, and after I noticed that nothing ever happened to this patient, I realized that all these people he mentioned were parts of his Self. The only evidence I had was my own feelings, but the problem was, how does one communicate this to the patient?

I ultimately gave, with some misgivings, the interpretation: "I think you are making me feel frustrated instead of you, so that you don't have any feelings of frustration." His immediate response to that was a burst of anger and hostility. I said, "When I spoke to you just now, you were not aware that I had spoken to you; you reacted exactly as if you felt I had blown words into you that you did not want." In this way we did make quite a bit of progress: it became increasingly clear that the analytic situation was not simply a conversation between two human beings; that is what it would sound like, and anybody could be forgiven for thinking that was all it was, but it wasn't. This is not an infant or child; this is not an omnipotent phantasy of the kind described by Melanie Klein. I think her description of it ought to be retained because it is valid, but there has to be a distinction between that and the experience I am trying to describe. It is very difficult to describe it to anybody who hasn't actually experienced it, but quite unmistakable if you are participating in it.

I have learnt from this sort of thing that the evidence made available to you by any patient who actually turns up is far and away of greater consequence than anything you hear said – hearsay evidence, evidence the patient gives you about other people. When I have interpreted these facts – that so-and-so had written a letter, descriptions about the relationship of this patient with somebody else, but nothing whatever about the patient – that was really falling for it and treating hearsay evidence as being of real importance. I suppose it is of real importance with patients who are less disturbed, or with whose lesser

degree of disturbance one is dealing, but I do put it in a very, very low category of analytic evidence.

Q: Is it possible that the situation you describe could be part of the unwanted self – the patient can't stand it coming back at him? Could it happen in cases where the patient feels there is nowhere to put that part safely outside and will then get attacked inside?

Bion: I think that does happen, but with some patients we have first to go through this stage I am describing. There is a peculiar reaction: the patient feels worse, and quite a number of people are drawn into the story wanting to interfere because he is so much worse. That is all outside the consulting-room, and I have no way of seeing how it is done. But I am sure that much the same methods are used as those I can see for myself in the consulting-room. In so far as the patient really does begin to take it back into himself, I think his resentment of analysis, of the analyst's interpretations, of himself for participating, does very much increase, and at that point so do the dangers of suicide. The patient is not so likely to make a physical assault on you – although I wouldn't rule it out, especially where lethal weapons are available – but he can make a lethal attack on himself. You can be called up: "Your patient is extremely ill; he hasn't eaten any food for at least five or six days." So you get an outbreak of what we used to call "acting-out". I am not quite sure now what I would describe as acting-out, partly because of the lack of any descriptive system of mental space. I *can* fall back on this when I am aware of the feeling of frustration contrasted with the patient who had none; there I can locate it and say, "Here it is." But when it stops and I am pursued with phone calls, interruptions and so on from elsewhere, then I cannot locate the places where it hurts. There still isn't a place where it hurts; the patient is not discommoded by having no food – the ambulance service might be if he fell down in the street and was found to be suffering from malnutrition, but in fact that hadn't happened.

I found out that the patient, who had been unable to get any employment for a long time, had found a job in a place where food was available and he *was* taking nourishment. It is very difficult to see why or how it was that everybody in the immediate surroundings had suddenly become aware of his malnutrition at the one time when he was getting food. I certainly think that there is a stage at which the resumption of the patient's murderous feelings is a dangerous one in

the analysis, one in which he is likely to kill himself in one way or another. This particular patient was not killing himself, but I see no reason to exclude the possibility.

Q: Is the difficulty of shifting yourself from feeling that the usual things are not happening in the consulting-room, to being able to see that unusual things *are* happening, what you call "catastrophic change"?

Bion: I think it is – yes. I am not sure in what way to approach this. One point is the difficulty of observing a change in analysis. I would now attribute it to the fact that I had not learnt that in analysis space has to be left for growth or development. I have to borrow these terms like "space has to be left" from ordinary language. I don't know what mental space is; I don't know any way of describing it, although I have given a paper[1] in which I talked about breaking up, breaking down, breaking through, breaking in, breaking out – take your choice. We hear people picking on one of them and complaining that they are "breaking down" or "breaking up". But the change of direction suggested when they begin to feel that they are "breaking through" is different.

Recently I had occasion to draw the attention of one or two people with analytic experience to the fact that they are beginning to believe that there really is such a thing as mental hurt. It is difficult to believe because verbal communications are carried out in a debased and devalued currency so that words like "anxiety", "embarrassment" and so on have very little meaning. Nobody really believes that they mean anything, but in the consulting-room "embarrassment" means mental pain. Sometimes you have to distinguish between different meanings of the same word; one that is commonly abused in this way is "sex", another is "love". "I had a lovely time", the patient says. You have to make up your mind as to whether the intonation with which it is said means that he had an experience in which he gained an enormous amount, or that at last he had an outlet to give something to somebody else. I think it is rare to find an analyst who believes both in mental pain and in the possibility of cure in the sense

[1][A talk given to members of The Study Centre for Organizational Leadership and Authority (SCOLA), Los Angeles, on 9 December 1975. The transcription, from an unknown source, of the tape-recording of the talk proved unsuitable for publication. *Ed.*]

of some sort of genuine relief. Of course, the worst of it is that the word "cure" is virtually meaningless; if it has any meaning, it usually refers to something nice or pleasurable – not the ability to be aware of the universe in which one lives. The change I refer to is the kind of development that is not gradual nor something that takes place all at once, but rather jerkily. "I *see*", says the patient, and sometimes you feel that he does – he *has* seen something. It is quite different from "Yes, I know". When it is that degree of exaggeration, it is very easy to detect, but most of the time it isn't easy to detect nor is it easy to distinguish between these various intonations. A musician might be in a better position to do that, particularly a singer. I think any musician could probably get nearer to detecting these minute differences in tone. When I say "minute", I really do mean something very, very small.

This idea of the Grid: a classification to sort out one's own ideas about the kind of communications being made is pretty gross. You would have to reformulate the Grid to suit yourself in accordance with you own experience. It is just a kind of preliminary suggestion. If you could turn the Grid edgeways on, then it would become nearer to being a grating; the space between these various categories would get smaller and smaller and smaller. [See *Bion in New York and São Paulo* (Volume VIII, p. 334).] So if you could imagine looking at anxiety/fear in that way, then the space gets narrower and narrower, becomes just a chink, and what is a gross difference between anxiety and fear, becomes a very tiny difference. It is these minute differences we have to detect. And now the observation becomes a matter of having a very fine ear to hear, probably reinforced by what you see. Those are two extremely primitive developments in terms of optic pits and auditory pits in embryonic development.

Taking the embryologists' gross description that the human embryo goes through this fish stage of existence, the amphibious stage and so on, you can see what a change there would be in the relative power of the embryo's – observation? perception? – I don't know what to call it because these words have to be borrowed from ordinary conscious speech and ordinary waking life. But a sense of smell becomes a long-range perception; a primitive creature like a shark is able to smell food from a very long distance in a watery medium. What the embryo can hear and see also changes its character

altogether; I haven't the faintest idea what to call it, but one day that person might turn up as a patient who was perpetually showing signs of something happening in the consulting-room without any explanation whatsoever. This sort of thing:

A. Well, what can I do for you?

P. But, doctor, I came here to find that out.

A. Yes, but I mean, what are you complaining of?

P. I thought you would tell me; I thought you would know what I was complaining of.

It becomes very clear after about the third question that you are on the wrong tack; it is no good pursuing that conversation any further.

What was that patient there for? Obviously you cannot know because you weren't there, but it would be surprising if it doesn't happen in your own consulting-room with one patient or another.

To take another example: I noticed after a long time – it took an awfully long time before I did notice it – that the patient was extremely sensitive to smell. I could detect this fairly easily; he arrived with all the essences of Arabia, and it seemed to be obvious that the smell he could not stand would be the one his untreated sense of smell could detect. After a time, such a patient begins to react at very short range; he is able to tell when he enters the room what is left over from the previous patient.

These same points apply to this matter of change in the emotional situation in the analysis. It is difficult when there is so much uproar of the past, of what you have seen in the patient before, so much evidence that you cannot detect the tiny changes until they have reached a striking proportion where the patient who couldn't work has started work (he may not have told you) and you are allowed to gather that by the smallest of possible hints, such as that he had difficulty in getting postage stamps. It is left to you to find out that he needed these stamps for a job he is doing – not just like that, but after several hours of work you can see it all adding up.

Q: Would the subtle signs that something is happening be in any way connected with the patient's fear of an unreceptive, rigid or hostile object that would object as soon as it began to feel that things were moving?

Bion: It certainly plays a big part, because these patients are not only improved but are probably sensitive in a way that most people are not. The result is that they can become painfully aware of the reality or hostility and envy. Whether they are able to stand finding out what sort of universe they live in will depend on how robust they are. I use the word "universe" to mean anything from their private and immediate contacts to the society of which they are members.

I would like to say a bit more about that from a rather different approach – namely "vogue", meaning by that a very powerful force. It is not recognized as that because usually these fashions – subsidiaries of the same thing – are extremely ephemeral. But vogue is not; it is a very powerful characteristic, one that carries with it a pressure to conform to the prevalent fashion. It may sometimes be delayed: the fashions of today won't become general for, say, another year, and then they become commonplace. Psychoanalysis was all the fashion at one time; psychoanalytic terms were bandied about with the greatest of freedom by people who usually didn't know what they meant and wouldn't undergo the long discipline required to find out.

In the same way, you find that you can become a fashion yourself – you are under extreme pressure to act or behave as if you were a person of importance when you know perfectly well that you are not, and you know perfectly well that that fashion will change in a matter of hours, days or weeks. It is the vogue, and for the time being you are under its pressure. It then becomes clear that the honours are showered upon you in the hope that you will not emerge from deep under to the abuse levelled against you.

The group therapist should always be aware that from time to time, as the fashion goes around the group, *he* becomes the fashion, and his ideas or what he says are treated as if they are important. If you are not aware of that, you are liable to believe it yourself; the intensity of feeling can always be made to rise to a point at which you, the target, cease to be able to think clearly. The most obvious example of this is in war, where you hope to intimidate your enemy so much that he doesn't think clearly. It is not quite so dramatic or obvious in full peace-time, but it is nevertheless still there.

The big component in this is what I call vogue, the basic thing behind fashion, fashions in ideas. It is against that kind of pressure that the developing patient has to contend. Sometimes it becomes

important to draw the patient's attention to it and say, "I think you are getting into a great deal of trouble because somebody is beginning to think that you are improving." When people become accustomed to the fact that somebody is neurotic or psychotic, they don't like having to change their views, because the person is now not quite so easily disposed of. Even a group – say of psychoanalysts, psychiatrists, psychiatric workers and so on – can always be in trouble if it is not possible to dismiss it as being a whole lot of crackpots. I don't think society would love us any more if it should turn out that, in fact, there are things we can contribute that it might not be possible for others to do.

These changes do seem to occur in little jerks – hardly perceptible, but adding up to quite a lot.

Q: Would you say that each little jerk has to break through something that resisted it?

Bion: Yes, but it is very hard to know what that is. I am reminded of the fact that Picasso could paint on one side of a piece of glass in such a way that there appeared to be a different one on the other side. I saw an example of this in a child's drawing: the child had drawn a picture and told me it was a house and a tree. On the other side of the piece of paper was a meaningless scribble, but if I held that picture up to the light, then the meaningless scribble shone through the paper and the picture was quite different; it was somebody watering a plant.

As I said yesterday, it is interesting and important to know that a child cannot understand mathematics and why 2 and 4 make 4; but what one would like to know is, what *do* 2 and 2 make? In other words, look at the other side of this so-called resistance; look at the resistance in such a way that what is being resisted shines through it. When it is quite clear that it is analysis that is being resisted, what is shining through that?

From the example I gave of the patient dying of cancer in hospital, it seemed to me most unlikely that he would want to spend such few hours as he had left on just blasting somebody – unless, of course, he had never achieved the good fortune to be dying of a fatal complaint. So it isn't simply a matter of "changing the vertex"; it is also being able to see through the resistance or countertransference or whatever it is. All those terms are obviously very useful, but in many ways the

analytic theories have been good enough to render themselves redundant. One seems to have to go through that process in order to make them redundant, to put them out of date, to put oneself out of date.

Q: I wonder if, implicit in what you are saying about the impact of change, in addition to his own resistances the patient also had to contend with the resistance of the analyst who, it sounds from your argument, would also have to change.

Bion: I think so, certainly. I have given the example before of people who thought that projective algebraic geometry was incompatible with Euclidean geometry. There are certain respects in which these are different, but algebraic projective geometry is *implicit* in Euclidean geometry. Now, thanks to Descartes, what was implicit in Euclidean geometry has been made *explicit*. The same thing applies in this mutual situation: I usually have to point out to patients that they cannot come to me for analysis without – whether they like it or not – having to analyse me. They may not like that because they don't know what sort of rage I might get into if they hit on the right thing; it is difficult to believe that the analyst would not take it badly in the way a child is quite used to: "I can't understand why you are *so* naughty"; it is made clear that when you are playing with your little brother or sister you shouldn't bash him or her on the head, you shouldn't bash each other; you ought to be playing nicely together. And so ought the analyst and the analysand. But, in fact, it is a pretty rough game.

Q: Could you differentiate between these kinds of processes of change and their consequences, from simply becoming maladjusted, losing friends and alienating people?

Bion: No, I don't think that is at all easy, because it again involves this matter of direction. Mathematicians tried to deal with this by the introduction of vectors. Analytically we haven't discovered a way of dealing with it, so we don't know the direction. People choose to say that the world is in an awful mess today. Next step: it is due to this horrible psychoanalysis, all this damned nonsense about people's minds and personalities – *that* is what causes the trouble. It is very difficult to refute. But it would be useful if one could get any sort of clue as to how to assess direction, or in what way to presuppose a mental state in which one was travelling in some direction. The

astronomers have decided that the solar system lies on one of the edges of the spiral nebula. The fact that there is no bright spot available at the centre is apparently regarded as what you would expect, because you can't see through the debris of the nebula itself to its centre. But it is supposed that beyond that, at a distance of 10^8 million light-years, lies the other side of the centre of ourselves. The scale of ephemeral creatures like ourselves is very hard to determine, very hard to see what direction is being taken by us. Indeed, with recent developments one could say that the human race itself is at the end of the road at a point where it is displaced by some other form of life. It is hardly a practical problem when we are dealing with these things on a relatively microscopic scale, not macroscopic – the macroscopic scales are not much use to us, but could throw some light on what is going on and on our being able to keep on the right track, assuming that there is a proper path for us to follow. Races which have a long history – such as the Jews, the Chinese – retain a certain cohesion so that they can get some idea about direction. But unfortunately these ancient cultures have also lost touch with their sources, their origins – or, as Freud put it, he doubted that Moses would understand his, Freud's, Hebrew.

It is a question of importance when one talks, as I do, about the truth. The answer seems to be so easily made, as Francis Bacon does in his essay: "'What is truth?' said jesting Pilate; and would not stay for an answer" [*Essays*, I, "Of Truth"]. We have to rely on our feelings; somehow at a certain point we feel, "Yes, that's right." Whether it is right or what the scale of reference is, or what the relationships to the truth are to the rest of truth, I don't know – and I don't know of any way in which we can get a grip on it. What we do know is that we are part and parcel of these vogues and can, to that extent, make some allowance for the pressure we experience.

Q: To what extent, in order to think the thoughts we think, do we require other thinkers at well?

Bion: It may fall to a particular individual to be able to formulate the thought or idea. But I don't think the actual germination of the idea can be attributed to any particular individual. It is very difficult to locate that. It crops up in practice chiefly with people who think that they own ideas and are very sensitive to plagiarism. There seems to be something in it – one would like to claim a certain ownership of an

idea, but whether that is anything other than the ordinary predatory instincts, I don't know. It could be part of the wish to grab, to carve out a sphere in the latest series of discoveries.

Q: I am wondering how much of what you have been saying approximates to the Jungian concept of the analyst as the agent or container.

Bion: The relationship of one idea to another is quite a difficult problem because ideas are not so clearly defined as words – and that is bad enough. For purposes of verbal communication you can do a lot with dictionary definitions and the rules of grammar, but when it comes to ideas themselves – the real thing, whatever that is – I think it is extremely optimistic to imagine that they also conform to the ways in which we think or even express our thoughts or ideas. It seems to me that this is one of the places where the formulist mathematician gets into trouble. The assumption is that the logical capacity of the human mind is of very great importance – and so it is to us for purposes of thinking – but the Intuitionists represent a revolt (Brouwer, Heyting and others) against that particularly rigid structure that doesn't really leave room for growth. The problem is that the work of the Intuitionists is so difficult for most of us to understand at all. Contrast this with geometria. I mean by that what is to us now a rather magical use of numbers. For example, you take the letters of which your name is composed; they are placed in the alphabet, and you add them up and get a certain number. You can play that game more or less indefinitely. It isn't geometry: it's a sort of – religious mathematics? I don't know, but certainly a mathematics that is employed and does come to the surface in developments where there is a theological turmoil, one of these spaces in the total area of human thought where an upheaval begins to surface. I am thinking of it in terms of the total area of thought, sometimes called mathematical, sometimes religious, sometimes biochemical and so forth. These areas of turmoil, of emotional upheaval, break out spasmodically over the total sphere. There you get thrown up characteristics that seem to conform to those in other emotional outbursts. For example, one of the manifestations of vogue seems to be the messianic turmoil. This is peculiar because the messiah often disavows it but it is very strongly advocated by a sort of prophet. The actual centre of that particular turmoil – the messiah – is strongly affected by something outside the centre; it is ex-centric, like

a situation where psychoanalysis itself becomes the vogue, and after a bit shifts onto somebody or something else – the latest vogue.

Q: Would you in this way be talking about psychoanalysis as the prophet of something that is much more central?

Bion: I think there is something much more central – possibly of a kind formulated by Schopenhauer, who doesn't say much about it but simply describes it as "the energy to exist". It can surface in this way in Freud and in psychoanalysis as one of these temporary bubbles on the total surface. As usual in these turmoils – like the period of adolescence in the individual – various features that have been latent or unobserved beforehand become apparent, sometimes negatively; for the time being the turmoil is noticeable by being suppressed, by not being allowed to emerge. I think that with Freud, Stekel and Jung there was an attempt to apportion out the areas that would be occupied by those three particular forces, but I can't say that I find the struggle for possession of some particular sphere at all enthralling or important.

Q: Yesterday you made an analogy with a blind person using a stick to find his way about. Could you describe the instruments you use?

Bion: No, I don't think so, certainly not anything I have been able to formulate. Somebody else might have a better idea of what I do use, particularly those who come to me for analysis. I am able to draw attention to the fact that coming to me for analysis is a vastly more unpleasant matter than coming to me for a supervision; it is a great shock to discover that. The actual close contact with an actual "me" is quite different from what they would suppose if they heard me talk. I can only suggest that anything I say about how I do it is probably somewhat misleading and off the beam. It has a lot to do with what I was trying to describe when I said, "When you are asleep you are in a different state of mind from the state of mind when you are awake." I am still talking about that when I refer to the patient who seems to behave physically in a way that could be seen as cataleptic. And the same thing applies to his state of mind: it is not dreaming and it is not wide awake. I don't know what it is, but it is very precarious and does seem to depend on being able to be on the edge of a precipice – to use a pictorial image. I think it can be seen with most

patients, especially in a prolonged analysis; you can get to a point where it is much clearer that they also behave in such a way that they are aware – particularly in adolescence – that they are frightened of going mad. Later it becomes much more a case of being frightened of being *called* mad; I like to flatter myself now that I am sufficiently used to being called that not to mind it as much. But I am not so sure that I would if I were in Soviet Russia, for example, or subjected to certain other cultural forces. It amazes me sometimes that analysts really seem to believe that they will be permitted to be psychoanalysts – I don't know why. I'm not sure that we all ought not to be prepared to "go underground", as they say. Milton makes great play of the image of Alpheus, the river that disappears and emerges from time to time in different places. [See also Seminars 2 and 3.]

Matti Harris: Perhaps we ought to stop now and all hope that Doctor Bion – who will, as far as we are concerned, have gone underground for the next year – will re-surface here next year at the same time and give us a comparable but different experience. I would like, on behalf of everybody, to give heartfelt thanks for the interesting time we have had. We have no doubt it has changed us in some way or another – we know not how.

Bion: Thank you. I hope not to be put under arrest when I return to California on the grounds of having changed so much.

Seminar 7

27 March 1979

[*The "winter of discontent" began with a wave of industrial action at the end of 1978; by early 1979 Britain was paralysed by strikes, and the normal life of the country came perilously close to a complete halt.*]

Bion: [*first part of recording missing*] . . . an establishment, shall we say, like the government of this country; then it buds off plenty more, called "devolution", and each bit of the devolved thing takes in a whole lot of other people – so you get bigger and bigger bureaucracies. In this respect I think we in psychoanalysis are well in the mainstream: there's the British Psychoanalytical Society, there's the International Psychoanalytical Association, there's the European Psychoanalytic Society, and I don't know what else – there are plenty of them, all of them presumably with their distinguished people, all of them with the distinguished people swallowed up in the administration, never having a chance of getting near a patient because they have to spend so much time organizing things. This raises a very difficult problem – that of whether people who are engaged in thinking can indeed combine it in any way, and, if so, how?

Q: I am wondering if the individual's thinking in his own time is different from that of the group's time.

Bion: What happens to your feelings, opinions, ideas and theories when, as here, we all come together? They would appear to be sunk without a trace, swallowed up in the group where we would hope to get some kind of discussion or clarification of the problems with which we have to deal. But the curious thing is that as soon as we are contained in a group, it seems to be very difficult indeed to go in the direction of developing thoughts or ideas or feelings of our own;

we are dominated by a need to be like everybody else and to think what everybody else thinks and feels – although how to tell what everybody else thinks or feels may be something we would find very difficult to formulate.

Somebody posed a question to me the other day – I can't say that I have found an answer to it, but I can pass it on. A small boy came for assistance, for help of some sort. As far as I could make out from the account I was given of this experience, on the one hand there was the analyst, and on the other this small boy who started drawing pictures with coloured chalks. The analyst gave an interpretation to which there was apparently no particular response; the small boy proceeded to draw another picture. And so it went on. He drew a picture of a lot of children on skateboards, but since I can't draw as well as he did, I do this [*draws a few lines on the blackboard*]. If I allow myself to get rather excited about it, I try to do another one [*draws a few more lines*]. Those are two signs, parts of my conversation with you. If you ask me what that *sounds* like, you probably couldn't hear I was producing my version of the *Blue Danube Waltz*. You couldn't hear it and I can't make the noise sufficiently clear here, not even with the apparatus of loudspeakers and so forth. I doubt very much whether you would recognize much more than a faint hiss. So one could say: that is the language, that is the pictograph, and the pronunciation of it is that funny noise I was making; that is how you say it if you want to talk it instead of drawing it. But suppose someone scientific came along: "Do you mean to say that that was a Viennese waltz, that row you were making? The Blue Danube? Have you ever seen the Danube? It's a dirty, muddy stream that moves at a tremendous pace. What are you talking about?" So there is this problem of the scientific view, the "true view", and then these various other views like my drawing of someone on a skateboard that certainly is not an accurate view. What is the nature of the communication? Which are you going to take? You can start making signs, like A, B, C – the alphabetic script – or you can start making pictographs, the sort of thing the Chinese do.

Freud called an international psychoanalytic meeting hoping it would be the start of an international communication between people. In fact, instead of it ending as he had hoped, it ended in all sorts of disagreements. Typical of that was the disagreement between Jung and Freud as to what was psychoanalysis and who was entitled to use the term. So there is this problem – as for example here – of how we

can see any particular way in which we can communicate with each other. Is there any common language that we can talk so that we can have a discussion?

Q: There is, apparently, a shared assumption about something called "the Establishment" that is "other people": they are powerful, they are boring and, above all, one must not be like that. If one actually looks at the people who reach a position of importance, it isn't very accurate.

Bion: No. The only accurate thing about it is probably the feeling of the individual who talks like that, but not necessarily, because individuals do not have to speak the truth about what they think or feel. But I think it is a fair assumption to suppose that the individual does try to communicate accurately – at any rate, in this sort of community. When it comes to groups of people at war, that is different; then they do not necessarily want to communicate what they think or what their plans are.

Are we somewhat prematurely and precociously attempting to achieve a kind of cooperative endeavour when in fact we are not really capable of doing much more than wage war against each other? Is it a matter of domination of who is top, who did it first, who is the owner, who possesses it? It depends on what sort of culture, what sort of civilization we live in.

To revert to the dominating silence, the thing that reduces us all to silence because we are frightened of expressing our true opinion or saying what we really mean – or, for that matter, meaning what we really say: if the Establishment, or the dominating force, is one that is exerted in the direction of making everybody conform to a particular attitude or outlook, then it matters very much what the nature of that culture or group is and how individual members – people who would like to be able to respect themselves and even, if possible, respect other people – are to compete with this pressure to be uniform, all to think alike, all to be equal. Péguy [1873–1914], quoting "*liberté, egalité, fraternité*", said [in *Basic Verities*] that two of those are completely different from the third; two of those aspirations are really worthy of pursuit, but not so the third [*egalité*].[1] I don't know if that gives

[1][I think it worth while quoting at some length from Charles Péguy's *Basic Verities*, which greatly impressed Bion: see Appendix on p. 91.]

any idea as to what bunch of thoughts, ideas or feelings would come nearer to expressing our present culture: liberty? equality? fraternity? That is simplifying the problem by tacking it onto those three terms.

Q: I feel that pauses and silences in a group play an important role in understanding – just as they do in music.

Bion: That is true, and in psychoanalysis also. Long ago I was asked, "Do you only just talk?" I said, "No, we don't; sometimes we are silent." Of course, that also has something to do with the beginning of the sound because the silence contributes a meaning to the sounds, to the rhythm. Even in silence we are giving a great deal of primacy to the verbal communication. I think it is reasonable because although it is a recent achievement, this ability to communicate by means of articulate speech – by recent I mean only a few hundred thousand years – seems to have been so productive that it can be looked to as a possible way of approaching the kind of problems with which we are concerned. That doesn't mean to say that it is an adequate method of communication. Hence one cannot very well say – though it is quite easy to do so – that because the small boy insists on saying nothing but just goes on drawing, he is resisting. Resisting what? He is merely disagreeing that the method of communication is verbal. He doesn't stop the analyst from making a verbal communication – he just goes on making a pictorial point of view, a pictorial communication. When it comes to huge bunches of people – like the Chinese – there it becomes a very serious matter if we think, "Oh, these Chinese, you know, this pictorial stuff, they don't even know how to write from left to right. These Orientals have nothing to contribute to our civilization." But when we have small groups like this, is there any chance of getting any further with this problem? Or are we all still dominated by the need to be "top", or to join the group that is "top", or to join the group or person who has the biggest number of possessions? Now we might almost say, "the biggest number of mental possessions" – that is to say, the area in which it is supposed that there are such things as creations of the mind. According to Plato, Socrates said he was merely a midwife, he merely helped people to give birth to their ideas. How much progress do you think we have made in the art of mental obstetrics? To what extent are we capable of tolerating anybody who could make a contribution? Or are we wiser to remain silent, to refrain from our own particular method of communication? I am not saying that

the only method of communication is verbal – that, unfortunately, is about all I am capable of – but there are plenty of people who are not so limited, who are capable of musical composition, of painting, or even of verbal communication of a very high order. But is this the sort of culture that promotes or makes possible the creative efforts of those who are able to create? Here we are supposed to be able to express our opinion on this matter.

Q: With reference to the child who went on drawing while the analyst was talking, I am wondering if that is real communication if it is not taken in by anyone else.

Bion: This is the problem. Supposing you have something to say: you unfortunately have to have somebody who is prepared to listen. If you are capable of painting, there has to be someone who will look at the thing – and as you know, most people don't. Most people will drift through famous galleries without a clue to what is in them. As an example, a person goes to the National Gallery and says, "I could have got through in half the time if I had . . . boots." That is one way of looking at the National Gallery – you don't have to bother about the paintings, especially as, if you allowed yourself to look at them, it would take up a very great deal of time. Of course, my example is ridiculous, but it isn't a ridiculous problem; in fact we don't have a great deal of time, and it is very difficult indeed to know how to apportion such time as we think we have available. That is one reason why, as an analyst, I would like to be able to express myself clearly so that the patient doesn't have to waste too much time trying to make out what on earth I am talking about. So in this curious way the exactitude of expression is likely to become a very demanding component, whether you are a painter or a musician or a speaker, so that you express yourself as economically as possible in the hope that someone will bother to listen to you and will be able to listen as economically as possible.

Q: As regards communication, the problem with art is to decide when it is not art. This question was raised in a recent controversy over a painting in the Tate Gallery.

Bion: I think you are right. It raises the whole question of discrimination because it is so important to be able to distinguish between the fake and the real thing. There are plenty of painters who are

extremely capable of giving a very good representation of, say, trees in a forest or a wood. But there is a great deal of difference between that and a painting of trees by Cézanne. I wouldn't like to say what the difference is, especially when we have all been taught to believe that Cézanne was a great painter – so we don't have to bother about that any more. But if we do bother about it, then we might tell the difference between a painting by Cézanne and a very technically able reproduction of it. That depends on this capacity for discrimination and the fact that it is very difficult to exercise it.

The attempt to use articulate speech for the expression of problems was by no means what articulate speech was elaborated for; its roots, the savage methods of behaviour, had to become civilized. We are still in the position of being savage animals who have to tame each other. But when violence is opposed to discussion, it does seem as if the outcome is doubtful, because the person who wants to discuss may have to defend himself, or the nation that wants to discuss may have to defend itself or even the right to speak. For example, psychoanalysis or communities of people who are wedded to discussion might become very unwelcome to the authorities. It could be regarded as subversive and an encouragement to people to have ideas of their own. You only have to look back through history to see the attempts that were made to suppress philosophical discussion or religious discussion, or any other form of discussion. But there is usually some little escape, like a seed pod, carried by the wind, that sprouts up somewhere else.

Galen [Claudius Galenus, c.130 A.D.–c.200 A.D.], a revolutionary thinker who really believed in observation of the human body, finally became a sort of god whose opinion was never to be questioned; free thought was suppressed, and anatomy and physiology stood still for generations – until it sprouted up in artists like Leonardo and Raphael who decided to look at the human body, the cadaver, and draw pictures of it. Then, through that kind of lateral expression, it came back to anatomy; anatomists again started looking at the human body. It is commonplace that students have to draw pictures of their detections; anybody who has been a medical student knows how much we disliked having to dissect and to draw accurate pictures of what we saw. Sounds simple, doesn't it? All you have to do is to draw what you see – don't tell lies about it, don't invent fabulous systems

of circulation and so forth, but draw what you see. But it is not at all infrequent for medical students never to recover from their experience of the dissecting-room. Do you think it is going to be any better with the dissection of the human mind, character or personality?

There would be something very queer about any analytic experience – whether one identifies with the analyst or the analysand – in which it didn't become clear that both parties dislike that occupation. It is not possible to analyse the analysand without being analysed oneself by the patient. So both parties are almost inevitably engaged in an occupation that arouses feelings of hatred and anger – not to mention also the wish to run away, to fly from that occupation. That is one reason why the future of psychoanalysis is always very precarious. Suppose it was suppressed and then leaked out again in, say, the direction of painters who depicted the character or the soul of the sitter. Only the other day I heard about Graham Sutherland's protest at the destruction of his painting of Winston Churchill. I dare say it would have been much better if he had stuck to photography because you can get away with it on the grounds that it is only what the camera shows. But a brilliant painter may depict the character, and this can excite a great deal of hostility on the part of the beholder. It isn't simply a question of finding somebody to listen to what you say; you also have to find somebody who will look at the painting that you paint. The little boy had to find somebody who would look at his drawings of people on skateboards. What is the analyst to do about it? If he sticks to making verbal interpretations, it can easily sound as if it is an attempt to maintain the superiority of verbal as opposed to artistic communication. Plenty of people have been written off as stupid or foolish simply because their methods of communication are different from what we ourselves are used to, or different from what we are able to understand.

Q: Coming full circle, I think analysts had better understand groups and institutions if they are going to understand their patients and the task they are dealing with, as well as dealing with the internal world.

Bion: In much the same way it matters if the diameter of the circle becomes so great that it may not appear to be the diameter at all because the segment of the circle seems to be very like a straight line.

In other words, the debate can become so wide that there is virtually no communication. Suppose all this kind of debate took place 10^8 million light-years ago: we have no method of communication with the past, and indeed it is difficult now to say what we owe to our forebears, who stopped using grunts and expressions of rage and fear and tried to communicate either by visible signs or some other method. I don't think that can be explained simply by Mendelian inheritance because, as I understand it, that communication would depend upon the inheritance of acquired characteristics. In other words, if we could start where our parents left off, and if we could leave off at a point at which our children could take over, then we might get an inheritance of acquired characteristics, we could become wiser people. Even aspirations like United Nations, United States, United Kingdom might begin to become realized; there might be such a thing as United People. There might even be an agreement about the need to promote the kind of activities pursued by philosophers, painters, musicians, poets, as part of a united effort, not so much as to who, which tiny scrap, has won the championship, as it were, but as part of the general mood. It took a very long time before we became as civilized as we are, and it may take a very long time still before we become more or adequately civilized. By "civilized", I don't mean like everybody else; I mean a situation where we could have respect for ourselves and other selves, while at the same time remaining part of the community.

Q: As I said before, analysts had better understand more about their own institutions . . .

Bion: I certainly think that if we can, we should devote such capacity as we have to things that are within our reach – in the sense of being near enough to be observable and comprehensible – so that we could at least make some contribution towards comprehending them.

In the experience of analysis it is curious how often we find that the analysand is most unwilling to admit the importance of any particular excellence that he has. Patients don't really mind devoting their attention to their crimes, their faults, their mistakes, and very often would like to get the analyst to agree to become a sort of "father confessor" to dole out appropriate penances. But when it comes to something the patient can do really well, it is extraordinary how often that same patient will denigrate it, dislike it and not want to pursue

it any further, on the grounds that it is too easy or that it comes "naturally", as if doing something that is natural is a sort of crime itself. There are many things that are natural to us – such as fighting each other – and it may be true that we need to be discriminating and decide what is desirable and what undesirable. Whether we can do so with any degree of accuracy is another matter; we simply have to make a decision in the light of our own prejudices. I have a prejudice: I remember a time when I was extremely anxious to join the army and get mixed up with the glorious occupation of war, but having tried shooting people – and getting shot at – I don't like it. I think there is still a good deal to be said for standing up for one's ideas.

Q: The army must be a group in which it is difficult to know what one's own ideas are.

Bion: Yes. I have known a person undergo the whole of army discipline and then give up the military career to become an actor. So it does happen that we join a particular profession and then chuck it up, but it is rare. Most of us may feel we have made a mistaken choice, but the upheaval involved in changing it, rectifying our mistake, is too painful; we would prefer to go on with the same profession, same theories, same ideas and not change them.

Q: Do you think it is really an addiction to go on with what we don't really like?

Bion: The only thing is to question oneself as to whether one is addicted or not. For example, I choose to be a psychoanalyst, but I wouldn't be able to say with any certainty whether that is simply an addiction – in the rather pejorative sense. I would like to be able to say that I am devoted to the occupation of analysis, or to helping my fellow men. But it is very difficult to know if one is devoted to a worthy object or has become addicted to that object. It is an on-going problem from which we shall never be free.

Q: Could you say something about the difference between "devoted to" and "addicted to"?

Bion: Take an example like being devoted to one's family welfare. While everybody may agree that the patient is devoted, when looked at more closely that same person doesn't give a damn what happens to the family as long as it contributes to the glory of the parent, so

long as the child does credit to its father or mother. I would call that not devotion to the family, but an addiction. I would want to introduce some sort of pejorative term into my own private formulation of that particular character.

Q: Would you say that it is a form of addiction if a person cares only about his or her own family, while the rest of the world can go hang?

Bion: One would have to have some idea about the motive of that person. It might be apparently extremely patriotic to want the welfare of one's own nation. But it is also true that if one's nation were well off, we would share in the general prosperity. There we are up against a profound problem – as we are in this subject all the time. It starts off as something simple, blossoms out straight away, and we then find that we are dealing with profound matters.

Is there anything particularly harmful in being a member of a nation that is well off and in sharing in the general prosperity? It doesn't do anyone any harm apparently. Eric Gill said that the best thing he could hope for the English nation was that it would become poor and impoverished. I don't know if he would have liked getting mixed up with the sort of traffic jams that I have experienced here – I would rather get here easily and comfortably without any fuss. So that particular statement of a general principle may be impeccable in terms of logic, but one does want the person who is stating it to practise what he preaches, and also to preach what is practicable. But the only person one has any control over is likely to be oneself. So we can try to live up to our principles – or to have principles it is possible to live up to.

Q: I have been thinking about the way we use time as a container.

Bion: Do we use time? Or does time use us? This is one of these extremely useful terms: most of us use it in a limited sort of way; we can look at a watch or a clock and schedule our day according to the number of hours we think are available. But when it comes to closer and more scientific investigation of what we mean by "time", it becomes clear that it is no good just looking it up in the dictionary. What do we mean by "time"? The point has often been stressed: "Time, like an ever-rolling stream, bears all its sons away; they fly forgotten, as a dream dies at the opening day" [Isaac Watts (1674–1748),

Psalms, 90]. There certainly seems to be some force with every one of us that contributes to the fact of one's birth and one's decline. We cannot really say it is due to time, but it is closely associated with the passage of time – as we understand it. The question should be much more, "What do you mean by 'using time', or by 'being contained in it'?"

Q: I had a patient who seemed to travel backwards in time. His material was all about the past and at times had been so repetitive that I might have one whole year of sessions of the same material, the same words. I really thought I would die with impatience and boredom. Instead of moving on in the river of time, he appeared to me to be on the bank, as if he hated time. I am thinking about the problem of tolerating someone who seems to hate time as much as that.

Bion: It certainly sounds like a peculiar kind of omnipotence if a patient feels that he can act a superior plot to all the rest of the flotsam and jetsam going down the stream, as if saying, "Yes, all these people go down the stream, but I – I'm saved; I've clambered out onto the shore." One wonders what sort of standards are being used there.

Q: It is comfortable.

Bion: Yes. You don't always have to take analgesics or hypnotics to be comfortable; you can achieve it with ideas. And indeed, it *is* comfortable to feel that we have now achieved a certain system of thoughts and ideas, and very *un*comfortable to feel that the whole lot of them might be upset by somebody who questions them – for example, by talking in a community like this. One can try to use one's theories as a sort of impenetrable armour plate.

Q: Do we have to tolerate social upheaval if there is to be growth?

Bion: I think it is fairly easy to say that there has to be space for growth or development if we stick to geographical measures, say of land, air, food, and so on. But the same thing applies to the domain of the mind. Falling back on metaphorical language, there has to be space available for mental growth. This habit we all have of wrapping our ideas around ourselves to keep out the cold so that we will never have another thought, never be upset by somebody else's thoughts, may be very comfortable, but it does not allow space for the

development of ideas. And if the unfortunate person who does that then grows, this comfortable state of mind begins to be restrictive, the suit of mental clothes becomes too tight – that is the misfortune in being the victim of these growth processes. Whether we like it or not, there is always the danger that we might have ideas or thoughts of our own, and those thoughts and ideas may want us to express them, want to be given a chance, an opportunity for expression. To fall back on the Socratic idea, there might be thoughts that want to be born, want to be aided out into a situation where they could grow and express themselves. So, from that point of view, every person has to be a midwife to his own ideas, thoughts and feelings.

The idea of being comfortable is very seductive – you only have to go outside to see the advertisements that are bombarding us on all sides to draw attention to how well off we would be *if* we had so-and-so's patent nostrum. There are plenty of invitations to be comfortable, but it is a problem to know how to discriminate between the fake and the real thing.

Seminar 8

28 March 1979

Q: I am wondering if there is a psychoanalytic way to the truth.

Bion: None whatever. Psychoanalysis is only a technical instrument, something we can make use of for any purpose we want – to make confusion worse confounded, or to mislead or deceive people, and so on. It all depends on who is making use of it. Is this building for the use of psychoanalysis, or have psychoanalysts been made use of in order to build this building? Are the available rooms conducive to the pursuit of psychoanalytic efforts? Or are they not?

The profound question in that is the problem of whether the person who purports to be searching for the truth is genuinely trying to arrive at the truth, or is a fake, an artificial representation of a seeker after truth. It is a very difficult question to answer. If you felt you could rely on your own judgement about that, then you might be able to tell whether somebody's paintings or writings are the work of a real genius. But as for the technical accomplishments of psychoanalysis, that doesn't tie you down at all – you can do what you like. Any idea that it inevitably causes you to speak the truth or discover the truth is pure rubbish.

Q: Yesterday you were speaking about patients' reluctance to talk about their own achievements. I am wondering why that is so difficult to do. Is it something linked with the harsh superego that prevents emotional enjoyment and development?

Bion: From time to time one can find various characteristics that seem to be related to obstruction. For example, this point where we can detect from a person's behaviour and discussion that there is a moral system emerging from it. We could say that the patient appears

to be dominated by very powerful moral impulses. If we had the opportunity to go on listening to and observing the patient, then it might become possible to draw his attention to the very important part that his morals were playing in the analytic experience. Perhaps we could go on further and get a bit clearer what kind of moral system this is. Psychoanalytically, theoretically and in certain religious approaches, it is also believed that there are very powerful feelings of guilt – original sin. But that sort of impulse seems to develop into a peculiar kind of moral system in which we can detect certain characteristics that do occur – namely, the moral system that seems to tell us what is wrong but never gives any inkling of what is right, that can be so dominant in the patient's mind that he doesn't dare to be or do anything. I say, "in the patient's mind", but it doesn't necessarily have to be so; I think it can also be in the society, an institution like this one, or the institution of psychoanalysis, or the Houses of Parliament – anything that can be dominated by this negative, prohibitive attitude. It is clearly described in the Book of Genesis and again in the story of the Tower of Babel, the idea being to find out what these creatures are up to, tell them not to, and stop it. That seems to some of us to be a very negative attitude, the kind of thing that is rather unimportant, in the way that a child doesn't know enough about running its own life or anybody else's to fill adequately the position of dominating the family. But one hopes that parents, who have more experience of life, may be prohibitory; they may often be reduced to saying, "Don't do this", or "Don't do that", but that is much milder than the kind of moral system to which I am referring. At some point we have to be critical of our moral outlook and ask ourselves to what extent it is, in fact, being prohibitive.

Q: Could you comment on the relationship between the internal process, and what sort of external requirements are needed to set the process going, and perhaps keep it in being.

Bion: In practice I find that it is important to be able to draw the patient's attention to just your question: it is surprising how difficult that is. The patient can express quite a lot of opinions and views, and it becomes clearer that he is dominated by some particular train of thought. But why today? What is going on? What has triggered this off? I don't know what words to use; I don't know how to draw the

patient's attention to the problem – namely, what has started him off on it.

Take one example: a patient expresses some degree of emotion, and the analyst says, "I think you are being affected by the fact that this is the week-end break when I do not usually see you", or it could be any other break in the analysis. If that is correct, it could be the trigger for that particular session's dominating theme. But in fact, it is very difficult to know.

A session may seem to be extremely disjointed: I have sometimes then been able to draw the patient's attention to the fact that he was just going to tell me something and was then interrupted. That interruption may be from outside – some noise or something I have done. But when that goes on happening, when I find that the patient cannot apparently pursue a train of thought at all, I wonder whether I am missing the train of thought he *is* expressing, or whether in fact he is constantly interrupted, constantly thrown off the road on which he is wanting to travel, the theme of his discourse, the theme he is wanting to talk to me about.

I'll try to imitate it: "Well, I was coming to the clinic just now – you know what I mean – there was a fellow on a bicycle, and he suddenly emerged from the side of the road and, er, well, er, that reminds me – the other day when I was going to talk to my son – now I've forgotten what I was going to say – er – let me think. Oh yes, I remember, yes, I think that this school to which he is going is very bad. They are always . . ." and so on. We have all encountered people who talk in that kind of way. You end up wondering whether you are talking to somebody who has something wrong with his mental apparatus, or whether he is in fact being interrupted and, if so, why? It can be that a person is very sensitive, has excellent hearing and is interrupted by noises from outside, but sometimes it is not so. Where, then, is the source of that interruption? You may not be able to answer that, but if you don't, this kind of patient still goes on pouring out more and more for ten minutes, a quarter of an hour, half an hour of disjointed sentences – it is impossible to see any theme running through it. Sometimes the interruption seems to be more permanent – not a series of interruptions but an obstruction amounting to a permanent blockage of the patient's train of thought – and then he has to find some sort of permanent circulatory diversion. If we were talking

about the body, we could say that the patient has an embolus; the arterial system has been interrupted and then there has to be set up a collateral circulation.

Such a blockage can occur in a very gifted child who may never get back again to its main capacity for expressing itself, whether artistic, scientific or whatever. But we hope that, with the analytic discussion, it may be possible to draw attention to that blockage, including this peculiar kind of moral blockage. We are not disapproving of a moral system, but suggesting that it could be a matter for discussion as to what this system is that makes it virtually impossible for the analyst to be right, for the patient to be right, for his family to be right, and so on in his various relationships. If we can do that, then we make it less necessary for the patient to resort to that kind of collateral circulation.

Q: Could you give me your opinion on the nature of envy as a component of a moral system?

Bion: No, I can't, because I think it is worth considering as being almost a fundamental, very powerful characteristic. You can see it where the patient – one hopes it is the patient and not the analyst – is so envious both of his analyst and of himself for making good use of the analyst that he cannot tolerate anything in the nature of successful or profitable analysis, even when he himself is one of the rewarded participants.

We unfortunately have to use these terms; it is one of the ways in which splitting has been turned to good account. We split things up – envy, hate, admiration and so forth – to make articulate speech more or less possible. But, of course, we don't in fact split up anything – these grammatical divisions and rules of articulate speech are quite all right for the purposes of articulate speech but not at all suitable for describing the human mind. I find it somewhat easier to think of envy and gratitude as being on the same linear progression; they are not really separable, but one is the extreme of the other, as if they were polarized, as if these sorts of feelings could be spoken of as polarized activities. [See Melanie Klein's "Envy and Gratitude" (1957).]

Q: I was thinking that in the first three years you came here the weather was very warm; my expectation somehow was that this time it would be the same . . .

Bion: . . . as long as you don't hold me responsible for having done it on purpose! There must be an explanation for this kind of weather; the meteorologists make an attempt at a scientific description of it. We can see on TV approaching low pressure just off the island there, and something else just off the island there, and between the two of them there are probably going to be fine intervals and a good deal of sleet and snow, and so on – most uncomfortable. It is an attempt to get to the truth of what it is that really affects the weather. But the truth is independent of us. Psychoanalysis is an attempt to know what it is that interrupts us, or makes it impossible to think clearly or to have any respect for the facts that are available to us; it is an attempt to investigate what it is in ourselves that causes so much trouble, not because we cause the trouble but because it is the only thing about which we can say anything at all. We can do nothing about these powers and forces that are out of our control. So if we are ourselves at fault, then it is useful to know what is the matter. "The fault, dear Brutus, is not in our stars, but in ourselves, that we are underlings" [Shakespeare, *Julius Caesar*, I.ii] – a most profound statement. Sooner or later there will have to be a method by which the faults in ourselves have to be corrected by ourselves. This is familiar to us when it comes to clinical matters: when we have a physical complaint we have to get some sort of help – an ambulance, a doctor or a nurse; that is commonplace. But it is a much more difficult problem with regard to defects in our method of thinking. There has to be created what we call a psychoanalyst, or something better – the name is not of much importance, but it *is* of importance that the "thing itself" should exist. There should be people to whom we could look for some sort of assistance about these "blockages", this fact that we are not necessarily stupid but that we don't seem to be able to think clearly. Actors can be afraid of "blackouts" or stage fright; it is the fear of these "interruptions" that interferes with their ability to exercise their technical capacity.

Q: With reference to your comments about the man running round the National Gallery and not understanding that there was something good on the walls, how can we make something available to someone who lacks this understanding?

Bion: I don't see any way in which we can evade that difficulty. We can know about its existence and be warned, have some foresight

about it. But in the practice of analysis it ceases to be a matter of theoretical, high-powered discussion; it becomes a matter of detecting it in the actual psychoanalytic episode when two people meet together with that kind of object. It is truly dreadful the way in which psychoanalytic theory can become so learned, so prestigious, that I would certainly hate to try to understand it myself; in fact, I don't waste my time trying to. I do occasionally get bombarded with it: while trying to say something to me, the patient is constantly interrupted by his own high-powered psychoanalytic knowledge. There is the same difficulty at the other pole, where there appears to be an inability to understand or to appreciate the reality of analysis. It is a curious fact that even in physical medicine doctors or surgeons can become callous; having to deal constantly with physical pain, they become almost insensitive to it. There are occasions when it erupts: I had the experience of a surgeon and an anaesthetist having such a nice time that they failed to observe that the child on the operating table had very nearly died. They suddenly ceased enjoying the joke and started putting emergency measures into action – unfortunately too late. [See *All My Sins Remembered*: Volume II, p. 40]

We can become callous to the actual nature of the pain, whether it is physical or mental. I know from my own experience that one loses sight of the fact that the patient is suffering – and you are helped by the patient to lose sight of that. A patient may be so amusing that the session is quite enjoyable; it seems almost unkind to remember that that patient has come because he is suffering.

The numbers of things that make the cooperation between analyst and analysand very vulnerable are legion – there is no limit to them. We can only hope to be able to detect, in time, whatever is menacing that particular attempt at a creative cooperation between the two people. One comfort we have is that, in a way, analysis is not very important; it is a temporary affair and a temporary association. So we can talk about "transference" and "countertransference"; it is transferred, it is on the way, but the real point about it is that people are constantly having an uncomfortable relationship with each other – it may be with a group of people or with an individual person – and frequently the obstruction to the comfortable or pleasant relationship causes a collateral circulation to set up. If two people cannot succeed in the aspiration to become husband and wife, then they can fall back

on the physical solution of it by turning it into a kind of successful sexual experience. I pick on that deliberately because we are so used to hearing that it is sexual inhibitions that cause trouble – and so they do. But sexual freedom also causes trouble; it is a method of finding a collateral circulation to avoid the difficulties of what one might call a spiritual relationship between two people – if that doesn't have too much of a moral connotation. But people can crave for a relationship that is additional to a purely sexual one; or they can crave for a physical relationship in addition to a purely intellectual discussion. I don't think these things are settled by simply feeling, "Oh, yes, sexual inhibitions." That is one possibility, but what we really need is to be able to detect where the blockage occurred and what form the collateral circulation has taken. I am sure that analysts who work with children must be familiar with the situation in which they feel that the real blockage is something between the husband and wife, and the collateral circulation is to send their child to an analyst. So the analyst + child is a kind of collateral circulation of something that lies outside that relationship. This is one of the complexities of our approach to these difficulties; that is why I say it is the old system of co-ordinates by which one can localize the pain. It is quite easy to flog away at the relationship between analyst and analysand, to go on analysing ad infinitum – as I said before, transference, countertransference and so forth – without really being able to locate where the real trouble lies.

Take this point about the weather: it isn't the only thing we notice on coming back to this country; there are also noticeable peculiarities of the state of mind. I don't know to what extent anything is done about that. For quite a long time I have thought it extraordinary that this is the only country to have fought two Great Wars from start to finish and not lost either of them. So it would hardly be surprising if we didn't now have to pay for that sort of luxury. Of course, I cannot pretend that that is a correct interpretation, or indeed that it is relevant; we do not know what are these changes in attitude, what the difference is between, shall we say, an England in which there is a belief in the British Empire, and an England nearer to conforming with what used to be called the attitude of Little Englanders. It is now little England, and the process of readjustment to these "facts" is very difficult. Anyway, we do not know what the facts are, nor what would be a readjustment on the right track. That seems to me to be

one of the reasons why the work we do is urgent and needs to have a realistic slant to it. It is hopeless if bunches of people meet together and argue about Kleinian theory or somebody else's theory – it is a pure waste of time because there are far more important matters to think about, or even to learn to think about.

APPENDIX

Extract from Péguy's *Basic Verities*:[1]

> "Not only are the three terms of the republican device, Liberty, Equality, Fraternity not on the same plane, but the last two, which are nearer to each other than both are near the first, present several notable differences. Fraternity obliges us to tear our fellow men from destitution. That is a preliminary duty. Contrarily, equality is a far less pressing duty. Whereas it is intensely pressing and alarming to know that there are men still in want, the knowledge that, outside of destitution, men possess more or less large slices of riches does not worry me. I cannot profess much interest in the famous question of knowing to whom bottles of champagne, blooded horses, castles in the Loire valley, will belong in the city of the future. I hope that this will be settled somehow. But I really don't care if so and so has such and such a position, as long as there will really be a city from which no man can be banished or held in exile by economic destitution. Doubtless many other problems will engross the attention of citizens, but to nullify the civic pact it would be sufficient that a single man be wittingly held or, what comes to the same, be wittingly left in destitution. As long as one man remains outside, the door slammed in his face closes a city of injustice and hatred.
>
> "The problem of destitution is not on the same plane, or of the same order as the problem of inequality. Here again, the old, traditional preoccupations, instinctive to humanity, are found, when analysed, to be much deeper, far better justified, far more real than the recent and always artificial manifestations of democracy. To save the destitute is one of the oldest cares of noble humanity, persisting throughout all civilizations. From age to age, fraternity, whether it puts on the guise of charity or the guise of solidarity; whether it is practised towards a guest in the name of Zeus Hospitable; whether it welcomes the poor as an image of Jesus Christ

[1] *Basic Verities*, by Charles Péguy, was first published in England in 1943 by Kegan Paul, Trench, Tubner & Co. Ltd. (Prose and Poetry in French with English translation by Ann & Julian Green.)

or whether it establishes a minimum wage for workmen; whether it invests the citizen of the world, introducing him by baptism into the universal communion; or whether by the improvement of economic conditions it introduces him into the international city, this fraternity is a living, deep-rooted, imperishable human sentiment. . . .

"Compared with this great sentiment, the sentiment of equality will appear small. Also, less simple. When all men are provided with the necessities, the real necessities, with bread and books, what do we care about the distribution of luxury? Sentiments of fraternity must be formidable to have held in check, since the beginnings of humanity, all the sentiments of war, of barbarity, of hatred, and to have won over them. On the other hand, the sentiment of equality is not an old sentiment, a perpetual sentiment, a universal sentiment of first magnitude. At determined periods it appears in the history of humanity as a peculiar phenomenon, as a manifestation of the democratic spirit. In a certain sense, sentiments of fraternity have always animated great men and great peoples, animated them, disquieted them, for preoccupation about destitution never goes without bitterness, disquietude. The sentiment of equality, on the other hand, has never inspired anything but questionable, particular revolutions. It brought about that English revolution which bequeathed to the modern world such a nationalistic, imperialistic England. It brought about that American revolution which established such an imperialistic republic. It has not inaugurated humanity. It has not prepared the city. It has only inaugurated democratic governments. It is a composite, mixed, often impure sentiment to which vanity, envy and cupidity contribute. Fraternity disquiets, moves, passionately interests deep, serious-minded, hard-working, modest souls. Equality often reaches only men loving the limelight, men loving publicity, and men of government. Or again, sentiments of equality are artificial sentiments, sentiments obtained by formal construction; bookish, scholastic sentiments. When violent passions, deep and broad, human and popular are roused on behalf of equality, as happened at the beginning of the French Revolution, it is almost always because formal equality coincides with realities of liberty and fraternity. It is a fact that, save for rare exceptions, the men who introduced preoccupations of equality into politics were not, had not been, destitute. They were middle-class men and poor men, notaries, lawyers, attorneys, men who had not received the indelible investiture of destitution."

THE ITALIAN SEMINARS

1977

The Italian Seminars, edited by Francesca Bion and translated from the Italian by Philip Slotkin, was first published in English in 2005 by Karnac Books, London. An earlier edition was published in 1985 in Italian: *Seminari Italiani: Testo Completo dei Seminari tenuti da W. R. Bion a Roma* (Rome: Edizioni Borla).

The Italian Seminars

EDITORIAL NOTE

The seminars contained in this volume were held by Bion in Rome in the summer of 1977. Parthenope Bion Talamo translated/interpreted at all the seminars – both Bion's English into Italian and the questions and comments from the Italian participants into English for Bion. It was an exceptional *tour de force* on her part. I subsequently edited Bion's contributions for the Italian edition of the seminars, which was published in 1985.

Francesca Bion
2005

NOTE FROM THE ITALIAN EDITION

The complete text of these seminars, held by Bion in Rome in 1977, has never previously been published in book form, not even in English. The seminars were carried out in two series: the first, consisting of four sessions, was held under the auspices of the Società Italiana Psicoanalitica; the second, of five sessions, was organized by the Via Pollaiolo Research Group.

Parthenope Bion Talamo
1985

Seminar 1

8 July 1977

First, I must apologize for not being able to speak Italian, but I am consoled by the thought that the subject I want to discuss is one which I find very difficult to talk about in *any* language, even when I am able to mobilize all the English that I know. I shall have reason to revert to this point later.

What are we concerned with? What are we all here for? What are we going to talk about? Of course, we could say, "psychoanalysis", but the word simply doesn't mean anything. It is a term which is used if we want to "talk about it", but it doesn't say what "it" is. You can't smell it, you can't touch it, you can't see it, and indeed it is very difficult to say what the sensible component of psychoanalysis is.

In so far as we claim to have a scientific outlook, it is usually supposed that there must be some supporting evidence. What I would like to touch on here is how important it is to have a foundation of fact, and how those facts should be observed by us.

My training in the British Institute of Psychoanalysis, my experience with John Rickman, with Melanie Klein – all of it was verbal. Are we supposed to be blind and deaf to everything except what comes in through the ears? When a patient comes to see me, there is, in fact, a body which I can see for myself, and to that extent I can fall back on the evidence of my senses and on the information which my senses bring me. I don't think that we can afford to ignore what our senses tell us, because the facts are very few anyway.

So far, the most valuable thing I have is the evidence of my senses and the information that my senses bring me. When I say "senses", I am borrowing a term from anatomy and physiology and using it as a model in order to be able to talk about other things for which I haven't the same sort of evidence. In this respect I am dependent upon having

a healthy nervous system which can be irritated – using the term in a physiological sense: our nerve endings are irritated by the universe in which we are living. Some of those senses are extremely powerful. For example, the sense of sight and ocular capacity appears to achieve a dominant role largely because I can see things even when I can't touch them. To some extent the same thing can be said about hearing: I can hear without having actual physical contact with a physical body.

I would like to draw attention to a quotation from Freud's paper of 1926: "There is much more continuity between intra-uterine life and earliest infancy than the impressive caesura of the act of birth allows us to believe" [1926d (1925), p. 138]. He had expressed it before, but he never seemed to follow it through; it came too near the end of his life. Also unfortunately – partly, I think, because of an intervention by Ernest Jones, who seems to me to have prejudiced Freud against Otto Rank – Rank wasn't really able to carry his ideas about the trauma of birth very far. He built up the trauma of birth: Freud tended to ignore the fact of that "impressive caesura". But Freud, being what he was, still appreciated that there was a truth in the fact of birth and the fact that it was a very impressive event.

I want to suggest that we should take the hint and make allowances for the fact that we are unduly impressed by the trauma of birth. I do it this way: When were you born? What was your birthplace? If you gave me the ordinarily accepted answers, I could say, "No, that is very useful for the vital statistics of the government who wants to know your birthday was on such-and-such a day of such-and-such a month of such-and-such a year. That would suit them fine." But I would like to be able to say, "Please tell me when your optic pits, at about the third somite, became functional. Tell me when your auditory pits became functional." Of course, I know perfectly well that nobody can answer that question.

I could ask a number of questions – I wouldn't expect you to try to answer them; I wouldn't try to answer them myself. Nevertheless, without a scrap of supporting evidence, I believe that they are relevant questions.

The embryologists tell us that there is evidence of the survival in the human body of what they call "branchial clefts". It is an interesting idea, and one could play around with it. But that would be more suitable if we had been – or were, or still had elements surviving in

our make-up which would be appropriate to our being – fishes. The embryologists also talk about vestigial tails. If these vestiges exist with regard to the body, why couldn't they be hanging around somewhere even with regard to what we call our minds? Is it possible that some of our characteristics would be more comprehensible if we were water-living animals? Or if we lived in trees like monkeys? It is not very difficult to see why people often talk – somewhat metaphorically – about our simian ancestors and our simian characteristics; not so often with regard to our fishy ones – although surgeons do talk about a "branchial cleft tumour". Although they are not operating on the embryo, they make use of what the embryologists tell us to carry out a surgical operation of a sophisticated kind on what they still call a "branchial cleft tumour".

What I want to draw attention to is this idea that the human animal has a mind, or a character, or a personality. It seems to be quite a useful theory, and we behave as if we thought it was more than that. When it comes to being psychoanalysts and psychiatrists, this cannot be treated as if it were simply an entertaining theory. Nor do patients come to see us because they are suffering from an entertaining theory. We could say that there is one collaborator we have in analysis on whom we can rely, because he behaves as if he really had a mind and because he thought that somebody not himself could help. In short, the most important assistance that a psychoanalyst is ever likely to get is not from his analyst, or supervisor, or teacher, or the books that he can read, but from his patient. The patient – and only the patient – knows what it feels like to be him or her. The patient is also the only person who knows what it feels like to have ideas such as that particular man or woman has. That is why it is so important that we should be able to hear, see, smell, even feel what information the patient is trying to convey. He is the only one who knows the facts; therefore, those facts are going to be the main source of any interpretation, any observation, which we are likely to be able to make. Our first consideration therefore has to be, how are we to observe if we take that scientific view of the importance of evidence – the evidence which is available to us for that very short space of time, fifty minutes or whatever it is, for which the patient agrees to make himself available? It is very important that every single one of us should decide for himself what is his minimum requirement in order to be able to do analysis.

It appears to me that the evidence which is available to my senses directly is worth incomparably more than the evidence which can be brought to me through "hearsay". To imagine a value, for the sake of this discussion, I could say that the evidence which is available when the patient is with me is 99%; what I hear said about the patient or my conduct of the case, or anything else, is worth 1% at most. So from that point of view, whatever I hear said or reported as soon as the patient has left my sight and hearing, I don't need to bother about very much; I can be deaf and blind to anything else. It saves a lot of trouble, I admit, but I think it also has a lot of sense behind it.

We now come back again to the questions, what are we observing, and what are we to do about our observations? I remember being asked, "Do you ever do anything besides talk?" I said, "Yes, I am silent." I'm afraid it may be difficult for you to believe when I sit here and talk, but in fact in analysis I like to be able to remain silent. It is, as we know, very difficult, because pressure is put on us to say or *do* something. "Why don't you *say* something?" "Why don't you *do* something?" This is particularly the case when one is dealing with a patient who is dependent – a child, say – on parents or relatives who want the analyst to do something. By that they mean do something which they can understand. It is difficult for lay people to believe that we employ a kind of talking which is indistinguishable from action.

We become so careless about our vocabulary in ordinary social contact that the words we use, the language we talk, becomes debased, devalued. I think it is therefore very important to get as clear as you can *your* language, the language which *you* use both for communication with yourself and for communication with somebody who is not you.

In your introspection I don't think it is a good thing to concentrate on writing what you think the patient has said – a sort of case history. That kind of narrative can be useful; I don't want to dismiss it, and perhaps we shall talk about it further later. But, in the meantime, think of what words you most often use in analysis, cut them down to fewer and fewer, and then use them very sparingly, very exactly, only in order to say what you mean. If you use very few words, and if you always use them correctly – meaning relating directly to what you think or feel yourself – then the patient may gradually understand the language which is spoken by you. Patients will often say to me,

"I don't understand what you mean." There are two possible answers to that: one is that there is no particular reason why they should, because they are not familiar with the matters I am talking about; the other is that they don't understand my use of those few words which I use. But it is very difficult indeed for patients to believe that I say what I mean. In a way they are quite right – very few people say what they mean. So it is hard to believe that that is what the analyst is doing. In time they may discover, extraordinary though it is, that the analyst is meaning what he says, or at least is trying to say what he means, which is very difficult. It is like doing a surgical operation and having to sharpen your scalpels and get them into working order *while* you are operating. So, while you are practising analysis, you have also to practise sharpening and making precise the vocabulary which you use. It is important to be sure what your vocabulary is, those few words which are really useful to you, and to keep them up to date and in a condition in which they can convey your meaning.

To digress for a moment: Why talk? It is a very recently acquired skill. I suppose the human animal has invented and developed articulate speech only in the last few thousand years – no time at all. So there is a great deal to be said for verbal communication and for keeping it as near to accuracy as we can get it. However, I don't think it is a good thing to ignore the fact that there are other forms of communication. Even verbal communication has been made by carving letters in stone. There are others who carve and sculpt shapes which are also methods of communication. Recently people like Henry Moore and Barbara Hepworth have carved shapes with holes in them. That is a resort to a method of communication in which there also has to be a receiver; it assumes that somebody will look at the sculpture. Similarly, painters use pigments – like the Impressionists. The Impressionist painters – and indeed all painters – are falling back on the communication of light; they can use varieties of colours, different ranges of the visual spectrum. It would be useful if you could consider for yourselves the various methods of communication that are known to you, their respective merits, and the extent to which they are capable of great subtlety.

I have talked for a long time, and I personally find it very difficult to tolerate information about questions I have not asked. Therefore, I think it would be a good thing if you could state what the questions

are that you *do* want to ask, and then between the lot of us perhaps we could find some kind of response.

Q: If you like, I can start, just to break the ice. Compliments and the like aside, neither I nor the rest of the group was prepared for Dr Bion's subject matter, but, of course, I was very impressed by the element of surprise, the form of expression and the pathos conveyed throughout. At the same time, I was quite surprised to discover that it fitted in with one of my own professional interests at this time – namely, the symbolic function of emotions. What I mean is the function of emotions as signs – that particular warhorse of late Freud – or a whole series of concepts used by Hartmann and other psychologists of his school, which have recently been taken up again by Rangell. I'm referring to the function of emotions as signs: emotions that perform an information function in themselves. Of course, it isn't the information function that sums up the content and meaning of emotions, although it certainly represents a good part of them. So when you talked about using the sense of smell, and all the senses, it seemed to me that you were somehow also referring to the possibility of nonverbal communication – that is, all the emotional forms we use to communicate both with ourselves (because they are intrapsychic symbols) and also, in a way, for communicating with others. Although they need not necessarily be translated into words, they also supply the patient with a reinterpretation of his phantasy or of the object of his perceptions. So I'd like to ask you now whether you would also include emotions among these non-linguistic forms of communication.

Bion: I think that what the patient feels is the nearest thing to a fact – as I ordinarily understand it – that he is ever likely to experience. The same thing applies to myself. For example, an infant seems to be "aware" – the best word I can use – of its "dependence". Inseparable from this, it also seems to be aware of being "all alone". I think both feelings are unpleasant, and I think they are both fundamental. An infant also seems to be aware that there is what we should call a personality present which it could depend upon; at the same time, that infant can be aware that there is not another person there.

With regard to patients who are described as being "psychotic" or "borderline psychotic", I think they are extremely aware of things which most of us have learnt not to be aware of.

Let us take that same infant twenty, thirty, forty, fifty years later. You, as the analyst, are getting a bit tired, so you fall back on theories, theories which I think are difficult to differentiate from what Freud calls "paramnesias", which are intended to fill this space which is left because somebody has forgotten some particular point and therefore invents something to fill that space. In that way one could argue that the whole of psychoanalysis is a kind of beautiful paramnesia worked out, made consistent with itself, a sort of architectonic in which every bit is in its proper place – only, here and there do there seem to be things which are paradoxes which start to emerge. When we are tired, our remarkably cosmetic conversation, which sounds exactly like psychoanalysis, in fact becomes jargon. In short, it is like the well-known statement that people try to make deep noises from the chest sound like profound thoughts. When this happens, the borderline psychotic will react in a way which shows that he knows that the analyst who was there has now become absent in mind.

I don't know if that is what you have been talking about, but it seems to me that it is very similar – this extraordinary communication. It is not physical, as far as we know, and yet an emotion is communicated from one body to the other – or, I suppose one ought to say, from one mind to the other.

Q: If possible, I'd like to take another look at the problem that was touched on at the beginning and go into it in greater depth – that is, the problem of the trauma of birth and the subsequent comments about the animal vestiges in human beings. After all, it seems to me that in what Dr Bion has said there is a kind of transition from the actual trauma of birth to what we might call the concept of a birthday: being born is one thing, but remembering one's birthday is another – that is, the moment when one began to feel, to see and to laugh. So I was very excited by this fact – whether the problem can be seen, to use Dr Bion's language, from this vertex. Dr Bion's emphasis on the need for the analyst to specify his own language to himself extremely precisely basically means, it seems to me, that the analyst must be absolutely sure that he is saying what he is really feeling. So when the analyst feels, more or less, that he is really saying what he is thinking and feeling, and therefore is genuinely becoming conscious of what is going on inside him, can this moment be compared with the transition from feeling to

articulate language that you mentioned earlier in the seminar? If this corresponds to the aspect of birth as a birthday – that is, not of birth in the sense of when one comes into the world, but of birth as the time when one becomes conscious of one's own perceptions and of what one feels – then the real question is this: might this process of self-specification and, as we might say, self-assumption of his own language by the analyst really be the analyst's repeated trauma of birth in analysis, and might the patient be in the position of a spectator of this on-going process of birth of the analyst? And finally, how can the birth of the analyst be linked up with the birth of the patient? What is involved in terms of identification, learning, nonverbal communication, and so on?

Bion: It would take me a very long time even to start answering the number of questions you have posed. But I would like to draw attention to a passage in Tolstoy's *War and Peace* in which Prince Andrei says, "That is sooth; accept it"; that is a feeling he has, and he communicates that feeling very clearly in those words. I don't know what validity is to be attached to it, but I do know that there are certain situations in the consulting-room in which *both* people are illuminated.

Translating the same thing into slightly different language: two people have a sexual relationship; they say – they can even get a licence for it – that they are married. Sometimes both of them have an experience about which they feel, "That is really an expression of love." In that way the two of them learn what passionate love is in an unmistakable manner, and measured against that experience you can re-assess all the other kinds of sexual relationships you have had – even with the same partner – and what a difference there is between them. Whether it is possible ever to bend this recently acquired capacity for verbal communication so that it could approximate to a description of passionate love is another matter. When you consider the cultural history of the human race, how many poets, philosophers, saints do you think have ever approximated to describing that extraordinary experience of passionate love? In fact, the words, the vocabulary, is so debased – so that many people have learnt how to talk about "love", "hate" and so forth – that it is a commonplace for people to say, "Yes, I know; yes, I know; yes, I know." They really think they do, but they don't know the first thing about it. It is possible to say, "Of course I know *Les Coquelicots* – I've seen countless

reproductions of it." Or, "Yes, I know Mozart's Horn Concerto – I've heard lots and lots of recordings of it." But they haven't experienced the "real thing".

After the last rehearsal of *Petrouchka*, the producer said, "No, it's not right." Both Fokine and Stravinsky were staggered by this idea that it wasn't right – it ended, if you remember, with the death of Petrouchka. When Fokine and Stravinsky attacked him and said, "Well, how ought it to end?" he said, "The ghost of Petrouchka must appear." So, although that was supposed to be the final rehearsal, they set to work again and changed the end so that the ghost of Petrouchka appeared on the wall, fantastically waving its arms.

What is that object which purports to be the ghost of an inanimate doll and which one would think had been dead all the time, having simply made gestures as if animated, pulled by the puppet-master's strings? Putting it another way: when you see your patient tomorrow, will you be able to detect, in the material which is available to you, signs that there is a ghost of a puppet? If you can, you may still be able to breathe some life into that tiny survival.

Q: I'd like to ask Dr Bion something. I have detected two smells in everything you have said here. The first was the smell of the things you said, which seems to me to be a smell of facts, and then there was another smell – in my view, a smell of theories. I'd like to know your personal impression of this and whether these two things are inevitably always mixed up with each other.

Bion: It depends what you mean by "inevitably". I think splitting has a very long history. For example, the diaphragm, separating the upper part of the anatomy from the lower part, was quite sensibly seen as the location of the spirit or soul because it goes up and down as one breathes; it's perfectly obvious that that is what makes people think or get frightened. So much for the anatomical facts, and so much for the ideas. It is quite rational, it is based on good observation, and it becomes an impenetrable theory until somebody penetrates it. According to Democritus of Abdera, the useless mass of the brain has something to do with thinking. You can see for yourself what a silly idea that is: it doesn't *do* anything. So a theory that the brain has anything to do with thinking is really fantastic and is unsupported by any evidence. Well – not quite, because some genius discovers that

if you tackle this brain matter, in spite of its bony covering, with, for example, a battle-axe, that will put an end to troublesome thinking. So there could grow up the idea that that drastic and violent form of operation reveals the source or origin of thought.

We have become so intelligent that I have heard it said that ideas don't exist in infants and embryos because the fibres aren't myelinated – therefore they cannot possibly think. But I have seen a very young baby who was frightened; I have seen a baby put on the pot and immediately "do its stuff". Does its bottom think? Or has it no myelinated fibres and therefore cannot? Or shall we have to reconsider our physiological knowledge?

The same thing applies to the whole body of psychoanalytic thinking. These theories are very useful – the difference between the conscious and the unconscious. Falling back on metaphor, one could say that when we secrete an idea, or when we produce a theory, we seem at the same time to lay down chalky material, we become calcified, the idea becomes calcified, and then you have another impressive caesura which you can't break out of. An asset, a useful theory of conscious and unconscious, then becomes a liability; it becomes a caesura which we cannot penetrate.

Dr Matte Blanco has spoken quite a lot about the possibility of thoughts or ideas which have never been conscious. I would certainly agree from an analytic point of view, from my experience of analysis, that there are certain ideas which appear never to have been conscious and which even seem to betray their existence in adult life. For example, I have a patient who talks very freely, and at the end of a session I know a great deal – if I were to attach much importance to hearsay evidence – about everybody except the patient. That seems to me to become a bit more comprehensible if one supposes that this patient has tried to get rid of every undesirable thought, feeling, even primordial thought, before he ever had them, so that he is surrounded, so to speak, by the thoughts which are voiced by other people – according to the patient – but never his own thoughts or ideas – never: he hasn't any; they have all been evacuated. One wonders if it is possible to mobilize what could be described as a mathematical capacity, or mathematical thinking, to express that state of affairs in a way that would be communicable to other people. Using as much analytic theory as seemed relevant, I made no difference

whatsoever to this flow of material in which everything appeared excepting the patient – the one object which was completely unexpressed. I have given plenty of interpretations about projection and so on and so forth; they make no difference. There is something about the total evacuation which requires some different form of approach.

A patient tells me that he has had a dream and that he dreamt . . . whatever it is. That is a narrative account. It could be described, borrowing from mathematics, as a linear progression from A to B. The individual is born, marries, dies. *Hic iacet*. There's the whole story – finished. But a problem arises when you want to draw the patient's attention to something which requires a more subtle delineation than a linear progression from birth to death.

Patients will very freely confess sins – lots of them – and after a time one feels that there is an inexhaustible supply of mistakes, crimes, failures with which to keep the analysis going. But if an analysis is turned into a somewhat elaborate version of the confessional known to the Church, it will not do. So even restricting ourselves to articulate speech, it is important to be able to decide when an analysis has turned into a kind of modern version of the confessional. If it has, then we may miss drawing attention to what the patient has got right.

I have experienced this curious state of affairs in which it would seem that the Freudian architectonic requires readjustment, particularly in the direction of leaving room for growth. While we are trying to elaborate a system of thought, or a system of analysis, we have to be aware that we are also excreting a kind of calcification which is going to make those thoughts become more of a prison than a liberating force.

Melanie Klein was rather annoyed at being labelled a "Kleinian"; she considered that she was an ordinary psychoanalyst and was simply following on the established theories of psychoanalysis. Betty Joseph said, "It's too late. Whether you like it or not you are a Kleinian"; she couldn't escape from that. And then, under the pressure of the various objections to her brainchild, she became more and more dogmatic and, I think, further and further from being able to draw attention to the merits of certain ideas which deserve to be given a chance to grow and develop.

This matters to us tomorrow when we see our patient. I think it is helpful to forget all our theories and our desires because they are so

obstructive that they become an impressive caesura which we cannot get past. The problem is how to let the germ of an idea, or the germ of an interpretation, have a chance of developing.

If I want to pictorialize this, I can talk about alpha- and beta-elements – a beta-element being something which is purely physical; an alpha-element something mental, like the idea that a baby is able to think if it knows what to do when a pot is put under its bottom. Take the next stage of the development, when it becomes something you can very nearly pictorialize: I would like to say, "Where did you go last night, and what did you see?" I am not really very interested in the fact that you went to bed and went to sleep. I would still like to know where you went and what you saw. Under pressure you might admit, "Oh well, I had a dream – but I don't remember it." Freud regarded the interpretation of dreams as being very important – it is hardly surprising when you consider how very early in history certain dreams have been recorded, such as those which appear in the Bible. However, while I agree, I think it is also liable to become – has, indeed, already become – a structure which is very difficult to break out of. When the patient says he "dreamt" something, we think – rightly or wrongly – that he was asleep. The places that he went to and the things that he saw were visited and seen, in a certain frame of mind. When he is wide awake and conscious he is in a different state of mind, and the story that he saw such-and-such is sure to be falsified because it is told when he is fully conscious. The experience was had when he was in a quite different frame of mind – "asleep" or "unconscious".

To come back to tomorrow's session: what you have to do is to give the germ of a thought a chance. You are sure to object to it; you are sure to wish it conformed to some cherished psychoanalytic theory, so that if you said it to some other psychoanalyst it could be seen to be in accordance with psychoanalytic theory, or the theories of your supervisor or your analyst. That is not good enough for what you tell *yourself*. Therefore – and this is really the central point, but very difficult – you have to *dare* to think and feel whatever it is that you think or feel, no matter what your society or your Society thinks about it, or even what *you* think about it. I can try to classify these thoughts and feelings as speculative imaginations, speculative ideas and speculative reasons. But I don't think that we should therefore allow ourselves to be misled into supposing that these speculative

thoughts have the same status as that which scientists ascribe to facts. As far as facts are concerned, I would think that they add up to evidence supporting a particular belief, idea or theory. The things I am talking about do not amount to anything better than a probability – something for which there is inadequate or insufficient supporting evidence. Even a person with as acute a mind as J. M. Keynes wrote on the Theory of Probability. But I am very doubtful that that kind of mathematics is good enough to further the problem of probability; there is something about the precision of mathematics which is valuable, but at the same time that precision must not be allowed to become so ossified, so calcified, that there is no room for development.

More recently, Brouwer and Heyting have attempted to release mathematics from the prison of present mathematical thinking by the elaboration of Intuitionism. Gödel has done the same thing with regard to meta-mathematics, which has involved questioning the law of the excluded middle.

I would like to be on the side of any of these things which have been excluded, whether it is the diaphragm which separates the top from the bottom, or whatever it is. Later I shall hope to talk about the excluded part of psychoanalysis, or what will be excluded from your consulting-room tomorrow when you and your analysand meet. The excluded part plays a large part and may not even yet have emerged into psychoanalytic theory.

Seminar 2

9 July 1977

Q: Before yesterday's seminar, I was curious to know what Dr Bion thought about music. I'd been reflecting on an analytic experience of mine when I felt that a woman patient preferred music to analysis and was trying – and had begun – to find music in analysis too, for certain reasons: music banished visual experiences, especially terrifying ones associated with the phobic space. She was able to dissolve the terrifying experiences of sounds by putting them together in a melody and using only certain sounds or certain limited pitches. If the music was broken down, the sounds took on a terrifying quality reminiscent of the terror of the visual, almost bodily, three-dimensional images of a claustrophobic space. But I had attributed this possibility of seeing terrifying images to her phantasy of a Cyclopean eye – the third mental eye that psychologists talk about – which she seems to see graphically before her.

An experience with another analysand puts me in mind of Ulysses, who turned himself into "Nobody" so as not to be seen and eaten by Polyphemus. So I wondered if Dr Bion feels we can also invoke a Cyclopean perception that has to do with music and analysis, as some psychologists have demonstrated.

Does Dr Bion think there is any connection between all this and the problem of musicians who play without reading the notes and others who can only play if they have a score in front of them?

Bion: If your patient is a musician or has musical capacity, then it is likely that in the consulting-room you can hear words *and* music. The patient's problem is not simply his relationship with the analyst. Obviously the analyst is a person the patient only meets for a few sessions a week for a limited period – it is not supposed to be

a permanent attachment. Then why does the patient come at all? It certainly cannot be because he disagrees with the analyst, or likes the analyst, for the analyst is not a person of any importance. As far as we are concerned, the real trouble is the patient's dis-agreement with himself. The psychoanalytic theory that there are mental conflicts is easily lost sight of but is, in fact, very important. However, as a temporary affair, what you can see is something of the relationship between those two people – the analyst and the analysand.

Falling back on the report of what happened – and this is what makes this kind of discussion of it of secondary importance – what would happen to you if you were bombarded with words as this patient bombards his analyst? Suppose the analyst is sensitive to what he is seeing and being told by the patient – that is what we are theoretically supposed to be. Taking first of all the words: what – as far as the analyst is concerned – are the nerve endings which are being stimulated? There is a wide range of stimulation of the analyst: the remnants of his classical education, knowledge of Greek mythology, knowledge or experience of any other culture. He is now free to show who he is by picking on, say, Greek mythology, or psychoanalytic theory or psychological theory. So from this point of view the analyst is invited to express his opinion of who he is.

What about the musical accompaniment of this mass of verbal information and stimulation? The patient is really giving a performance of a full operatic experience, of words and music. The problem is, what is the analyst to do? Whatever he does, the patient will have something to go on, something the patient can then himself interpret.

Again identifying oneself with the analyst: what are you to do when you are bombarded with such a vast variety of mythology, story, classical history and music? There is the further point that the analysand probably knows that the analyst is medically qualified; he can therefore always stimulate or not, as he chooses, the medical knowledge of the analyst. For example, this particular patient might show bodily symptoms of a blood disease. What is the analyst to do when he feels that the patient needs medical treatment and, at the same time, the analyst wants to be an analyst? I pose the question because those in a sufficiently hostile community will be very glad to bring accusations of malpractice against the doctor who has failed to interpret that the trouble was not mental at all, but that the patient had this, that or the other blood disease. I have known this happen:

the analyst was accused of having failed to diagnose that it was a case of cancer and of having gone on – according to the patient – mistakenly interpreting in psychoanalytic terms a cancerous condition which finally destroyed the patient.

I should be suspicious about so much "noise" made by a patient who bombarded me with such a mass of facts. The analyst can be deafened, blinded and put in the position where he virtually cannot use his senses because they are *all* being bombarded.

Suppose the patient shows signs of physical disease but just passes it off. I think in that instance I would say, "With regard to the physical complaint you have made, you will, of course, be seeing your doctor. But *here* we must consider something else." Out of all this variety of material from which I am invited to choose, I would like to select what appears to me to be psychoanalytically relevant. That is quite simple as a general theory; in practice, it is not. In such a mass of information the noise is so great that you cannot hear the noise you ought to be hearing. The impression that it creates on me is that if I were subjected to that experience, my attention would be drawn to the repetition of this word "terrible" – it kept cropping up. I would strongly suspect that this is the vestigial remains of something that I would regard as sub-thalamic fear. I am not using that phrase as an expression of my medical or psychoanalytic or any other knowledge. As far as I am concerned it is an idea which belongs to what I have described as "speculative imagination".

Now that is all very well for me: it is not good enough for me to transform my impressions into a psychoanalytic theory, or a psychoanalytic interpretation. Therefore, I would want to hear more, and the minimum condition for me to analyse that patient is to be allowed to remain silent, because I don't want to add my noise to that which the patient is already making. *If* I am allowed more time to be silent, then I may be able to hear just a little bit more.

The situation in analysis is misleading because there is apparently only one person there with the analyst. I have found my experiences in groups useful – a group is almost like one person, character or personality, spread out over a space. In a group I would want to know, "Who is this person who is saying, 'terrified . . . terrified . . . terrible'?" Similarly, if I were a physician I would want to see the whole body, and then perhaps I could locate a swelling, or a flush of the skin, and I could wonder, "Is this some sort of infection?" As

I say, in the group one could then locate, so to speak, the origin, the source, of the infection.

Having taken that sort of group view, narrow down your observation. At this point I would be paying much more attention to this "terrible" and listening to the occurrence, apparently, only of a word; but I would hope, if I am given a chance of remaining silent, to be able to detect a certain similarity about all these "terribles". And then when I thought that things had gone far enough for me to feel that I could formulate my observation, I would do so. But I would ignore all the rest of it.

However, there is still this point that included in this is also the music. The two of them together would perhaps make it a bit easier to see or recognize the centre of infection, the point which really requires to be interpreted. That is much more difficult than it sounds in a discussion like this. The experience of practical analysis or practical medicine, or the practice of anything, is very much tougher than the discussion about it.

Q: Someone told me about a psychiatric institution where, over a period, a professor gave identical red sweaters to a number of mothers, who held their babies in their arms until, after a while, the sweaters were taken back and placed together on a carpet. Then all the babies were put down beside the sweaters, all of which were the same colour, and quite a few were able to find their mother's sweater, presumably by the smell. But then, the head of the institute where I worked for many years boasted that he could identify a person's schizophrenic state from the particular smell he or she gave off while in that state. I had never experienced this and doubted that it was true, until one day I was analysing a schizoid, perverse patient, who had great difficulty in expressing some of his feelings in words: it turned out that in some sessions he was putting out a very particular smell, which tended to put me in a dream-like state in which quite disturbing images came up in my mind. I mention this because it seems to me that we have had a lot to say about nonverbal communication here.

Bion: The nonverbal communication is very difficult to interpret, to transform or translate into articulate speech. That applies both to the analyst and to the analysand. The analysand likewise expects that he will have to talk an articulate language with his analyst, and he hasn't

any words with which to do it. This happens in a variety of different ways – here, we can discuss it again, not only with regard to this particular patient, but to recognize a certain similarity between that kind of communication and the patient who responds with floods of tears. Tears, like smiles, don't mean a thing. So the analysand is up against this problem of finding a method of communicating what he wants to say. Falling back on a narrative view of the situation – from birth to death – smell can be one of the long-range methods of communication. Therefore, some stage in the development of the patient – or, as I would put it, some aspect of this patient at the present moment – still betrays a survival of that state, or what I am compelled to call "a state of mind". Where is this smell located? Anatomically and physiologically we can produce all sorts of theories based on our knowledge of embryology and so forth, but, ignoring that for the moment, where is it cropping up with these apparently two people in the room? I say "apparently two people" because of the dominance of what one could call a rational point of view – there are only two anatomical structures in the room. But it is difficult to know how many minds or personalities there are there, and which one is the source of that smell.

Again indulging in speculative imagination, I would say that this patient finds it very difficult indeed to say that he is coming for mental nourishment. If he could by any chance re-mobilize extremely primitive equipment, then perhaps he could smell the place where he expects to find mental nourishment. But suppose that, at the same time, the patient is afraid of making a smell which would make *him* locatable so that something could come and prey on him. In that way I would begin to suspect that he is sometimes afraid that he will get devoured, and sometimes afraid that the analyst will notice that *he* is being fed upon, being used to provide mental nourishment.

Then why not say so? Why not say that he wants an analysis, that he wants to have his emotional or intellectual needs satisfied? The obvious answer would be, "Because he can't." Articulate speech, which can be comprehended by somebody else and which the patient can understand, is not available to him. So he is afraid that there is no chance of getting the help he wants from the analyst. This is a very common state indeed. I still find it astonishing how few patients believe that any relief can be obtained. And the same thing applies to analysts: they do not feel that they have any evidence that the kind

of conversation that takes place in analysis will satisfy anybody or anything. It takes a long time before it becomes clear that, in fact, the analytic intercourse is yielding an experience which is nourishing to both parties.

The same thing applies to the patient who repeats "terrible, terrible". All that is said in a vague hope that somebody or something will turn up who will be able to understand what he is communicating and will be able to supply the correct mental nourishment. It is a matter of touch and go whether the patient will be able to come to analysis long enough to find out if it is worth doing.

The kind of thing I have been saying is something of a generalization. From day to day, from free-association to free association, one is dealing with a little bit of that fundamental story. In the one instance there is this problem of how to find something to feed on without getting eaten up in the process; in the other, how to let anybody know that he is terrified, especially in a situation where there may be nobody. In this way both patients resort to a somewhat obscure, primitive and incomprehensible method of communication. Then they can feel, "Well, nothing comes of it, but it doesn't matter. It's not worse than it was before." But if the analyst has been able to give enough interpretations to lead the patient to think there could be somebody who understands, then terror is released.

To make that point clearer, using a pictorial image: a party of some five people were survivors from a shipwreck. The rest had died of starvation or had been swept overboard from the remnants of the raft. They experienced no fear whatsoever – but became terrified when they thought a ship was coming near. The possibility of rescue, and the even greater possibility that their presence would not be noticed on the surface of the ocean, led them to be terrified. Previously the terror had been sunk, so to speak, in the overwhelming depths of depression and despair.

So the analyst, in the midst of the noises of distress, the failure of analysis, the uselessness of that kind of conversation, still needs to be able to hear the sound of this terror which indicates the position of a person beginning to hope that he might be rescued.

Consider this patient who smells the possibility that the analyst could nourish him, but also that the analyst might devour him. Let us put that into more rational terms: will the analyst understand

him? Or will the analyst shut him up in a mental hospital so he will never escape? What interpretation do you give? This highly sophisticated one, saying, "You are afraid of getting locked up in a mental hospital"? – in which case he might not understand why the analyst is talking like that or what it has to do with what he is saying. That question can only be decided by the analyst or analysand, or both of them, because it is such an extremely subtle position. That is why I don't like butting in with theories which are out of touch with the actual patient and the actual experience. I would again say that the more the analyst appreciates the extremely wealthy circumstance of an actual session to which the patient comes, the greater chance he may have of being able to make up his mind: "No, I won't give that interpretation, I'll give this one."

If I say he is afraid of getting locked up in a mental hospital, it may frighten this terrified patient so much that he cannot go on with the analysis. Or if I say he has no sense of smell, the situation would again be hopeless. It is necessary to give an interpretation which lets the patient have a chance of knowing that he has been understood, and a chance of feeling that he will not be incarcerated or devoured.

This is partly a by-product of the fact that, thanks to articulate speech, we do seem to establish a contact, a verbal intercourse. Therefore, the patient who has these terrifying experiences can be afraid that the terror will be communicated to the analyst, and if he, the patient, doesn't run away, the analyst will. Falling back on the group experience, I can say that the patient is afraid of a situation which can develop into fight or flight and can express itself on sophisticated levels of the mind of the analyst who says "Oh well, I think you are cured" and finishes – in other words, runs away – or gets angry and says "Oh don't be so silly; don't be so ridiculous."

I think it is necessary to interpret the patient's relationship with himself. He isn't simply frightened of being eaten up by the analyst or the hospital; he is frightened of being eaten up by *himself*. For example, suppose the patient finds that masturbation has a very soothing effect and that the anxiety is somehow relieved by the stimulation of his own genitalia. Then comes the fear that the pleasures of masturbation will take possession of him, that he will go mad – a very common fear we come across where people are able to express feelings of fear of going mad but don't usually know why. It can generally be traced to their fear of a pleasurable or rewarding experience.

To revert to the point I made yesterday: the importance of the analyst's ability to provide the space in which he can develop. Whatever body of theory attracts you, you should also consider whether there is room in it for the expansion of yourself. You should not be afraid of these speculative imaginations and speculative reasons, which are extremely vulnerable and which can be destroyed with the slightest inclemency of weather, so to speak. If you find yourself speculating and imagining that this or the other story is relevant, you should allow yourself to entertain that speculation in the hope that it might grow into a communicable idea.

Q: May I ask Dr Bion if his suggested methodology, involving something in a constant state of renewal and ferment, or rather *in statu nascendi*, might be connected with the Eastern tradition, or have something in common with it? I'm thinking of the kind of teachings that gurus or yogis pass on to their followers. After all, what happened before strongly suggested this to me.

Bion: I hope so, because I am somewhat distrustful of a method of treatment which suddenly springs out of the ground or springs out of the sky. I don't know why, but I have a prejudice in favour of acknowledging my indebtedness to my ancestors. I don't think I mind very much if I am accused of ancestor worship – I still would like to be able to acknowledge some sort of gratitude to my forebears.

Let us take a previous inhabitant of this city: he says, "*Vixere fortes ante Agamemnona multi, sed omnes illacrimabiles urgentur ignotique longa nocte, carent quia vate sacro*" [Many brave hearts lived before Agamemnon, but they drove to that long night unhonoured and unsung for lack of a sacred poet – Horace, *Odes*, IV: 9]. It is comforting to feel that our brilliant psychoanalytic theories are not necessarily a barrier which, while no doubt establishing our superiority to our ancestors, cuts us off from them for ever. I have no complaints about the complacency which is engendered by a feeling of success about achieving an analytic insight, but it is a great pity if it becomes ossified or fibrosed into a kind of impenetrable diaphragm which separates us for ever from our ancestors. If Horace could acknowledge the existence of poets long before him, I don't think there is any harm in our also acknowledging the existence of our predecessors even though they were never heard of.

Q: I'm pleased to say that, whereas yesterday Dr Bion was suggesting that we search for an object, today he has given us some coordinates, some positions, to help us get our bearings. So I wondered – to return to the people on the raft for a moment – whether something that might be useful to them is the idea of reversible perspective. It would be like providing them with an optical instrument to allow them to see more, rather than showing them an object. Let me give an example. In a group, there was a situation that went on for perhaps ten sessions where a girl spent the entire two hours of the session panting. Now (the whole thing was totally opaque to me at the time), from what has been said, it seems to me that what was needed was to find a different way of looking at the situation or, at any rate, first of all to overcome my inability to think. Later, when I realized it had to do with cowardice, I felt I could suggest to the group that it should look at the situation not from the medical and sacrificial point of view, but in terms of the impossibility of developing in a dimension of past and future. I merely wanted to add that it is an attempt to communicate.

Bion: The analytic situation stimulates very primitive feelings, including the feelings of dependence and isolation; they are both unpleasant feelings. It is not, therefore, really surprising if one of the pair, and probably both, is aware that the psychoanalytic raft to which they cling in the consulting-room – beautifully disguised, of course, with comfortable chairs and every modern convenience – is nevertheless a very precarious raft in a tumultuous sea. Besides the various theories and interpretations to which the analyst gives expression, there needs to be an awareness that the two people are actually engaged in a dangerous adventure. There is always a tendency to snatch at some piece of material – some psychoanalytic theory or idea – as a kind of lifebelt which would help to keep the two feeling that they are still alive and floating. A common piece of wreckage is the idea of a "cure"; we snatch feverishly at the latest bit of cure that is available in order to keep afloat. That is something the analyst should be able to resist because, while it may have a temporarily curative effect, if it is constantly repeated then it becomes an addiction – the pair get addicted to cures. And in this peculiar sphere with which we are concerned, there are any amount of cures floating around. So it is a good thing if the analyst – in so far as he identifies himself with

the responsible person – resists too many of these cheap cures which can be built into an elaborate structure so that, before you know where you are, the raft which is made of bits of wreckage turns into a delusional system which is a veritable *Titanic*. As we all know, the *Titanic* was unsinkable, it was the latest thing – but it hit up against a fact, and that sank it.

Mathematically, lines, circles and so on were profoundly changed by their translation into vectors, directions. I would suggest this: let us consider for the sake of argument that this experience here is a fact. Working our way back through speculative imaginations, speculative reasons, can we get back to the dream that we haven't had yet, tonight's dream, the dream which originates in the fact of this meeting? If we could do that, then we would be in a position to trace back the train of thought which might help to explain how it comes about that we are all in this room just now. This "fact" is one which ought to be classified as "incredible". If somebody wrote, or could write, the story of each individual member of this meeting and say they would meet in this particular room, in this particular hotel, at this particular date and time, anybody reading that story could only say, "How ridiculous!" There is no story which is so unbelievable as the true one.

Q: After the comment on the question of the ancestors and the quotation from Virgil and so on, I found myself thinking about yesterday's Freud quotation, in which he seemed to be emphasizing the continuity between intrauterine life and early infancy, rather than the caesura of birth, on which a lot of stress had been placed.

Now in Dr Bion's presentation yesterday, when he mentioned Otto Rank's concept of the birth trauma, I thought he was suggesting that we are "too impressed by the trauma of birth". On this point I disagreed with the interpreter, who interpreted that we are *not sufficiently* impressed by the birth trauma. Could you please enlarge on this point, as I don't want to make too much noise.

Bion: I am not aware that I was stressing either being impressed or not being impressed by the caesura of birth. I wanted to suggest that the caesura of birth, the anatomical and physiological fact, has a dominant effect on our view of whether the mind also is born at the moment of physiological birth.

When you are in the state of mind of the person who is awake, with all your senses about you and conscious, what relation does

what you *say* you dreamt have to the experience which you had when you were in a different state of mind – namely, the state of mind when you were asleep? I am sometimes told that the patient had a "dream" and that, for a fact, such-and-such happened. I am not so certain that "in fact" the patient dreamt it, nor am I so sure that the "facts" are as he described them. There are plenty of things we can call it: dream, delusion, hallucination and so on. The words have become so debased that they are virtually meaningless, and if they *are* given a meaning, that meaning is virtually useless. So it is hardly surprising if the patient we heard about earlier thinks that there is a lot to be said for the music. You may sometimes wonder why a patient comes to see you, and why the patient starts telling you whatever he tells you. As a step on the journey it may be quite useful to have an analyst who, the patient can say, thinks this or that – it is a relationship between two people. But it is really a relationship that the analysand has with the analysand. The highly intelligent embryo sees and experiences whatever it sees and experiences; the highly intelligent man or woman also gives a very convincing account of what is taking place. A difficulty would arise if by any chance we could introduce this highly intelligent postnatal person to the highly intelligent embryo who could tell such very different stories, different narratives about the same facts. If the "unsinkable" *Titanic* could meet with its passengers, those it sank, I wonder what the dialogue would be. If they met *before* that unfortunate fact, they could say, "I had a terrifying dream." One could reply, "Don't be so silly – it was only a dream." I leave it to you to imagine what they would say *afterwards*.

Seminar 3

10 July 1977

Q: I'd like to ask Dr Bion if he can tell us more about his ideas on the countertransference, because it seems to me that this is the particular type of noise in the analyst's mind that can be picked up in the psychoanalytic experience. I wonder if it might also contain musical elements, and if so if we should adjust our minds like a high-fidelity system that can not only extract the signal from the noise, but also act like a resonance chamber and allow us to receive the entire range of acoustic stimuli, even if that means that the clarity of the melody is lost.

Bion: The idea of the transference and the countertransference has been extremely productive, provocative and growth-stimulating. But, like every really good idea, like anything which provokes or stimulates growth, it makes itself out of date at once. When individuals are exposed to the analytic experience for the first time, they don't understand what that experience is or what its name is. Nor does the analyst say, "You are experiencing transference to me" – that is a technical term which is useful for people who have already had the experience of psychoanalytic training. After a time, though, the novice begins to understand that the analyst is drawing attention to an actual experience which he is having. If he is becoming an analyst, then he may reach a point where we could say, "That is what we mean by transference – that is a transference manifestation. Your feeling that I am your father or mother can be compared with other ideas you have: you can bring together both the idea that I am your mother or father *and* the idea that I am a stranger whom you do not know. Then you can decide for yourself who or what you really think I am – that is your affair. In that way a new idea is born. The idea

that you had before – namely, that I am a blood relation, a father or mother – is transient; it is a temporary idea on the journey of your life. From that point of view the technical term "transference" can be seen to have a resemblance to ordinary usage. It is an idea that you have "on the way" – you transfer it to me as a temporary measure on your way to what you really think or feel. At the same moment the new idea that you have is a temporary one and will be discarded sooner or later. It is another of these places where you stop on your own particular journey. If you could look at these various ideas which you have in the course of this experience with me, you might be able to trace a sort of map showing the stations of your journey from point A to point Z. Where you are now, when you have just seen this point, is already out of date."

Consequently I would say that the idea of transference and countertransference is hardly worth mentioning to this audience. That would be suitable if we were concerned with writing the history of psychoanalysis; then it might be interesting to say, "Transference, as defined by Freud is . . . Transference, as defined by Abraham is . . . Transference, as defined by Melanie Klein is . . .". In short, may I hand you the *Encyclopaedia of Psycho-Analysis*. You will find all the definitions laid down here if you want to know the history. But if you are, in fact, having a psychoanalytic experience – that is different.

Nansen was asked, "How did you get to the Pole?" His reply was something like this [*draws on the blackboard*], "That's my route." That is a pictorial representation of how Nansen discovered the North Pole; that is how he got there; there's the map. He drew it much better than I have – although he had just had a very good dinner. In the actual experience of analysis there isn't time to do that; there isn't time to carry out this sort of discussion. Once the patient begins to understand what the analytic experience is, then he changes so fast that what he thought or felt at the beginning of a sentence is out of date by the time he has reached the end of it. That is why, when you are satisfied that the patient is actually developing, it is as well to be able to forget what you know and to discard what you want to happen. It is difficult to de-barrass the mind of its load of experience; we are liable to slow the patient down by clinging to out-of-date ideas and, as a result, are unable to watch the patient's progress to some other idea.

As I said yesterday, I think it is as well to be able to acknowledge our debt to our ancestors – our mental ancestors. It is quite appropriate for us, as analysts, to know what was meant by "transference" or "countertransference" when used by Freud, Abraham, Melanie Klein or anybody else, only if at the same time we learn how to forget it all so as to be open to the next move which is made by the patient – the next stopping station, as it were.

The patient who has very gifted genetic ancestry – a very intelligent father and mother – is the product of what the biologists call "sexual relationship" between that particular father and mother and therefore develops from a germ which has chromosomes derived from both parties. If the development is adequately expressed in physical terms, then it can be worked out in terms of that sort of inheritance. But if there is such a thing as a mind or spirit or soul, that may not follow the same laws as those of Mendelian inheritance. As psychoanalysts who believe in the existence of a mind, we then have to consider what are the laws of inheritance of the mind. Provisionally, transiently, on the way to something better, I would like to suggest something like "phenotypes" as contrasted with "genotypes". By supposing something of that sort, we might be able to work out the laws of, the inheritance of, acquired characteristics which according to Mendelian theory are not transmitted. I suppose the existence of speculative imagination, speculative reasons, for the early development of those characteristics which are mental, which, as I have already suggested, have a different form of inheritance from that of the genotypes.

Every single one of us would be hard put to it to write down his or her mental journey and mental inheritance. Who or what were your ancestors? I don't want to hear about your genetic ancestors – what are the other ones? Could you have a look at your character or personality, this queer thing which I am sure exists? I am convinced from my experience – partly as an analyst, but on the whole through life – that there *is* such a thing as a character or a mind. I don't think I am always affected by the physical appearance of the person, although, thanks to the dominance of our eyes, the cosmetic element is likely to play a very big part and we can immediately be affected by the feeling of liking or disliking somebody. We don't even have to go deeper than skin-deep, literally or metaphorically: "I don't like

that person – he's white" (or "black"). It would be a ridiculous situation if a doctor refused to examine a patient who had a cachectic flush or showed signs of inflammation or of jaundice. As doctors we are expected not to take such a prejudiced view of what the body tells us, because our examination of that body is supposed to be more than skin-deep. The situation is not so very different if we are supposed to be concerned with the human mind or character or personality. If we are sensitive to this supposed "thing", then the fact that we don't like that person – or that character or that personality – is irrelevant. We are nevertheless supposed to know some more about that character or personality, whether we like it or not.

As analysts we have to be disciplined to a situation where, whatever the facts are, we do not allow them to make us run away or do the opposite – fall in love. We are supposed still to remain analysts. We are not obliged to become inhuman people who cannot love or hate: we are still supposed to retain the capacity to have feelings of love and hate and all the other feelings which go with them, but at the same time we are supposed to remain disciplined. To take an extreme example such as battle action: an officer is not supposed to be afraid, but that does not mean that he does not know that a situation is dangerous. Nor yet is he supposed to be so carried away by a victory as to assume that the war is over. That is one reason why I suggested last time that we are surrounded by the wreckage of cures all over the place – the remains of the wreckage of the disaster in which somebody has been sunk by cure, sunk by his desires, misled by his hopes and fears – whichever part is showing above the surface, like the iceberg. As the poet [Arthur Clough (1819–1861)] says, "If hopes were dupes, fears may be liars."

Have we any coordinate system which could give us an idea as to where we are, where the pair are – the analyst and the patient? In the narrative story we can get an idea of a person's development by taking any two points, A and B, and the direction would be from A to B. Those two points, A and B, we could call "real and distinct". However, suppose those two points were mobile; then they might travel round the circumference of a circle and become "real and coincident", And if we try to draw in the two points which are real and coincident, we can say that they meet and describe a line which is a tangent.

Take these two people – the analyst and the analysand – who have met at one point. I don't know what spiritual route the analyst

has taken, the journey that his mind has taken between the point at which it is supposed it began its existence and the point at which it became coincident with an entirely different personality – coincident and real. Let us suppose that these two points go on with their journey: the analyst and analysand continue to live; they don't stop at psychoanalysis; they don't stop at this point at which they are real and coincident. I was taught to call that "conjugate complex". I didn't have – and still haven't – any particular ideas about what to translate that into. I am glad to find that even my translator here had to hesitate for a moment. However, I use these two words "conjugate complex" as imaginary points. I am assured – and I hope there is a mathematician here who can inform me more correctly – that these imaginary points still obey the laws of real ones. In that way I think we ought to consider, as if it were real, that the analyst and analysand still continue to exist even when the analysis is over, when those two points, which are real and distinct, real and coincident in the analyst's consulting-room, continue in a space about which I know nothing because that mind which is no longer in contact with me has gone I don't know where.

Q: Thinking of this alchemy of human existences and encounters between thoughts, I wonder if Dr Bion can explain to me the role of the human need to know – what I think he calls K. And, second, what part is played in the patient by the need to express to someone his desire for knowledge?

Bion: I suspect that these are vestiges of fundamental characteristics which have not yet been destroyed either by the inability to tolerate ignorance or by the inability to tolerate the answer. The trouble about curiosity is that it is liable to provoke a response. From what I know of myself, the danger to which anybody exposes themselves by asking me a question is another flood of questions. I do try to resist the temptation to say, "Yes, I know; I know about transference; I know about countertransference." I am partly assisted by the fact that I *don't* know. That picture in which Nansen showed exactly how he got to the North Pole does not tell me – and I would never know – what it would be like to be Nansen wandering in the wastes of the Arctic. I only know a little bit about what it feels like to be me wandering in the realms of the human mind. One hopes that it is a relatively limited sphere – not quite so dangerous, perhaps, as wandering in the realms

of omniscience or omnipotence. There are various pictorial images, narrative images, fables, in which it is supposed that the attempt to eat of the forbidden fruit of the Tree of Wisdom excited the highly dangerous wrath of omnipotence and omniscience. To be dominated or motivated by curiosity, by our wish to know, would seem to be a dangerous occupation, especially if we come across another mind which has the characteristic of omniscience or omnipotence. As Milton put it, "who durst defy th'Omnipotent to arms" [*Paradise Lost*, Bk. I]. As analysts we may be always running the risk of questioning whoever or whatever is clothed in authority. It is not only the psychoanalytic investigation which is suspect, but also any activity which might be seen as arming ourselves by improving such minds or instruments as we have available for investigating the unknown.

Q: Let me take up Dr Bion's image of the analytic couple who meet at a certain time at a real, coincident point, and later split up so that each, as it were, goes off at a tangent. Dr Bion says that the couple nevertheless continues to exist, but he doesn't know how and where. I wondered if what happens is the transformation of a relationship which, as between the analysand and the analyst, is an object relationship, and if this object, which goes off at a tangent, later becomes a spatialized object – if it becomes an area or a space. And this applies to the analysand as well as to the analyst. In other words, I wanted to ask Dr Bion what relation there is between a relationship with a real object and one with a spatialized object.

Bion: I doubt whether any of us would ever know, because we are so ephemeral, so short-lived. One feels that we, this group, have some existence previous to this meeting. You can put any number of years to it if you consider that the calendar gives you an adequate measure to go by. But a few orbits of the earth around the sun is a very insignificant method of counting time. Similarly, the distance from Los Angeles to Rome is too small. So the measurements of both time and space are simply not adequate. These two "things" – I have to borrow from the language of material objects – leave the consulting-room and go out into space and time. It is difficult enough to find a coordinate of geometrical space; it took several hundred years before the Cartesian co-ordinates were produced, and then really by accident. The co-ordinates of the time and space into which these two characters or souls or personalities – again, I am not even able to give a precise name

to it – are launched are very difficult to describe. Even our imagination is not free if we try to imagine what would be occupying this space, here, in the relatively insignificant time of two thousand years ago, who or what was occupying what we now call "Rome". But the same thing applies to this space which is occupied by "Rome" and what it will have turned into in two thousand years' time – which, as I say, is a relatively insignificant time span. As far as absolute space is concerned, the astronomers imagine that the solar system will have completed its journey when it has made one revolution around the galactic centre. The most recent estimate that I have heard is that the diameter is something like 10^8 million light-years – quite a long time. Nevertheless, I suppose we can add some minute bit of knowledge to this problem of the coordinates by which we could plot the course of these two people when they leave the consulting-room.

I would like to mention an example, which I have often used, of the kind of thing that I mean. Hugh Kenner was talking to a yokel in Warwickshire and mentioned how beautiful the dandelions looked. The yokel replied, "Yes, we call them golden boys and girls, and later when the petals fall off, we call them chimney-sweepers." Hugh Kenner was familiar with a song from *Cymbeline*, two lines of which are, "Golden lads and girls all must, / As chimney-sweepers, come to dust." The Warwickshire yokel, without any education, was using a language which must have been commonplace in Shakespeare's time. So Shakespeare may have been making a commonplace remark – "as chimney-sweepers come to dust". I don't know what Shakespeare could have been thinking . . .

[*The remainder of this seminar is missing from the recording*.]

Seminar 4

13 July 1977

In some ways it is an advantage to me to know that I don't know any Italian, because I think you can be misled by thinking you *do* know Italian. Patients *seem* to talk French, or English or Italian, but what *we* want to hear is not any of those languages. I find it difficult to say what language we need to listen to; the nearest I can get to it is to say that it is the language of what Freud would call "the unconscious".

I have seen this stated most clearly recently by Dr Matte Blanco, who mentions this peculiar fact of Freud sometimes talking about "the unconscious", and at other times talking about something as "unconscious". They are two different things. Furthermore, I have come across material which seems never to have been what Freud would have called "conscious". Dr Segal described a situation in which a patient says it is obvious that somebody who is playing the violin is masturbating. I had a patient who, I began to feel, wore his mind inside out – that is to say, like clothes worn inside out: what ought to be on the inside is on the outside. Falling back on metaphorical language, I could say that the patient behaved as if his unconscious was outside. So the interpretations which we would think appropriate formulations of unconscious thoughts and ideas are, in fact, ordinary statements to the patient. He has no difficulty whatever in thinking that the analyst is saying things which are obvious. On the other hand, if we resort to ordinary speech, waking thought, conscious thought, the patient says, "I don't know what you mean." He has no difficulty in understanding a psychoanalytic interpretation of something we could regard as "unconscious", but he cannot understand the language we talk when we are wide awake, fully conscious and aware of what we call the "facts", "reality".

I used to find this difficult to understand – I still do. I also found that it made me angry. I thought I preserved a disciplined attitude and was quite polite, but the patient had no difficulty at all in knowing that I was annoyed. That was also annoying – I didn't like being analysed by my patient. But I persisted, and so did the patient.

After a time I drew the patient's attention to the fact that he had not said why he came to me or what he wanted me to do. His reply was, "I have been telling you all the time. You mean to say you don't know now?" Well, I didn't. I felt I had to do a lot of thinking about this extraordinary situation. Why did the patient keep on coming? I didn't know.

Another patient complained strongly about the behaviour of everybody else. Thinking of this in terms of projection, I tried to draw his attention to the fact that everybody was wrong, but that there was nothing wrong with him. There again, thinking over the matter, I couldn't understand why he kept on coming. If the situation was that A, B, C, D and so on were so hostile and so difficult, what was *I* supposed to do? What was I supposed to interpret? There is nothing I can do about a universe in which everybody is wrong. The inhabitants of this world don't all come to me for analysis; the one person who does come has nothing the matter with him.

I searched my mind in the hope of finding some interpretation which would appear to approximate to this situation. I thought of the various interpretations which Freud gives – particularly those dealing with *the* unconscious, the repression of conscious ideas, the filling of the gap, the space occupied by amnesia, by paramnesias – but it wasn't any good. I thought of Melanie Klein's idea of projective identification – an "omnipotent phantasy" that the patient believes he can evacuate his thoughts which are out of control but which nevertheless persecute him. I gave various interpretations in accordance with that theory. I couldn't see that it had any effect whatsoever. So the problem was, is psychoanalysis any use at all? Why give these interpretations – Freudian, Abrahamian, Kleinian and so forth – none of which has any effect at all?

It seems to me that the one essential in analysis is that we should be able to go on thinking in a situation which is extremely tense. We are bound to be anxious about our ability to treat and, at the same time, about our apparent inability to do anything about the fact that

either the theories of psychoanalysis are wrong, or the idea that the correct interpretation will cure the patient is wrong, or that something else which we do not know is wrong – or all of them.

I would like to continue the discussion in a way more applicable to what we want to know or think about before seeing tomorrow's patient. I shall be glad to try to go on from there on any theme that you wish to introduce. I could sum up the question by saying, "Where do we go from here?"

Q: Dr Bion's comments on nonverbal communication put me in mind of something that Paul Valéry said: that the entire substance of what people say lies in song and in the sound of a voice, yet these are often disregarded, neglected. I'd like to connect this with the problem of distance and time in analytic work – when we might be either too close to the patient or too far away from him, and when we might say something either too soon or too late. As to the patient mentioned by Dr Bion who asks "What do you think of this?", I would ask a question: from his own experience, can he give us an example of a situation in which he answered immediately and another where he felt it was better to wait?

Bion: The question goes to the root of the problem – namely, what is the space or time that we are talking about and are in? What coordinates can we suggest for locating the source or origin of the difficulty?

Can we observe the "thing itself"? Milton says in *Paradise Lost* [Bk. III],

> So much the rather thou Celestial Light
> Shine inward, and the mind through all her powers
> Irradiate, there plant eyes, all mist from thence
> Purge and disperse, that I may see and tell
> Of things invisible to mortal sight.

We are mere mortals, mere human beings, so how are our minds to be irradiated by celestial light so that through all their powers they are illuminated, enabling us to see (first point) and tell (second point) of things invisible to mortal sight? Our problem tomorrow is, how are we to see, observe – which is regarded, in any case, as the first requisite of a scientific outlook – these things which are not visible? How are we to see the invisible and then formulate what we see in such a

way that the patient can see what we want him to see. There are two points: the first is to be able to see it ourselves; the second, to find a mode of communication so that we can tell the patient.

Are we able to be scientific at all in the sense of observing the facts? Up to a point we can. We may have a patient who is flushed: in other words, in so far as his body is communicating and if we have enough medical experience and training, we are able to observe a flushed appearance on the cheeks of the patient which a lay person couldn't see. We can teach medical students how to observe. We say, "You must examine the patient; you must look at him; you must ask him to remove his clothes so that you can palpate his body and in that way understand the language spoken by the body – that is, diagnose the condition." It doesn't seem to me that that is in any way different from the analyst who is trying to interpret the mind. Physically we call it "diagnosis"; analytically we call it "interpretation".

In saying that, I have made an entirely artificial separation; I have talked about the body and the mind as if they were two entirely different things. I don't believe it. I think that the patient whom you see tomorrow is one, a whole, a complete person. And although we say – obeying the laws of grammar – that we can observe his body and mind, in fact there is no such thing as a "body and mind"; there is a "he" or a "she".

To take up this other point about distance: what is the distance between "there" and "here"? What is the distance between the state of mind which is repressed and the state of mind which has done the repressing?

The same thing, put in a different way: what is the distance between the person, awake and conscious, who says, "I had a dream last night", and the person who, in a different state of mind, experienced the dream? Suppose the sleeping person is restless, twists and turns because he is aware of a pain. It may be because he has appendicitis, or it may be because he has painful thoughts or ideas. When he tells us that he had a bad dream, where do you locate the discomfort? Is the source of that discomfort physical? Or is it what we call "mental"?

That is your problem tomorrow and all the other tomorrows. The only person who knows the answer to that question is your patient. Therefore he is the one collaborator on whom you can really rely.

If the patient is suffering from leukaemia, he doesn't know enough to understand what his body is telling him; he is dependent on a doctor, or a psychoanalyst, or both. A doctor, if he is well-versed in medicine, and if he knows how to observe, can see that there is an infection, something producing an inflammation; that is what his patient's body tells him. What are psychoanalysts to observe? How are they to be aware of these pains? And, then, how are they to see them – the total situation, body *and* mind, one person? In the consulting-room the analyst is all alone; he can depend only on such powers of observation as he has and on the patient. Similarly, the patient has nobody on whom to depend except the analyst. Therefore this *practical* situation, the *practice* of psychoanalysis, involves the relationship between two people – but, half a minute: is it only between two people? Anatomically, physically, there are A and B. Is that real? Are there only two people? If we look at and listen to what is in the room, what shall we look at? The patient? Our own free associations? Our own ideas as to what this is? Or a *relationship* between two people? It is *at least* two people. Is it what Dr Matte Blanco calls a "symmetrical relationship"? Or is it something else? That seems to me to be a matter which can only be decided by us who practise psychoanalysis. It is no good looking at books about psychoanalysis – there is no time. This has to be observed in your session tomorrow.

Perhaps somebody here could formulate the nature of this problem still further. I think it is a mistaken idea that there is some analyst who knows the answers. I now know quite enough to know that I don't know. And in spite of all the pressure to which I am subjected to know the answers, I *don't* know them. But I am sure that between us all we may learn a bit more and be a bit wiser by tomorrow evening.

Q: The problem of communication and non-communication – the aspect of the limits of communicability – centres on the patient rather than on the analytic relationship. Otherwise it might be possible to do something about the different potentials of certain analytic couples for development, which sometimes favour the development of the analyst as well as the patient. Here one really feels that the things that are developed are very close to primary repression – aspects that have never benefited from contact with reality. This potential often impresses its stamp even on the intake session, so that the analyst sometimes feels compelled to take on

a patient he had not previously thought of accepting for analysis. Perhaps it is precisely this situation which results in analyses that are productive for analyst and patient alike.

Bion: No one should set up as an analyst or doctor unless he is prepared to pay the price. To put it in other words, "If you can't stand the heat, keep out of the kitchen." Once you want to help your fellow men and women, you are in trouble. It doesn't matter how ill you are, how tired, how mentally or physically sick, you have to preserve your discipline. I gave the example of getting angry with a patient. It doesn't fool the patient. That is *not* good behaviour on the part of the analyst – he has to continue to behave in a civilized manner.

To take a more extreme situation: the officer in war whose troops are frightened and want to run away. The officer is not privileged to run away too. His privilege is to stay where he is, even if it costs him his life. That may seem to be an exaggerated description of your session tomorrow with your patient. I don't believe it. I think it is hidden because the psychoanalyst's consulting-room is comfortable, he has good food, and so on. But he can be so overwhelmed with noise – putting it again metaphorically – that it is difficult to hear. The noise comes from within – hypotheses about physical illnesses, hypotheses about analytic theories – masses of them ad infinitum. They all make such a noise that it is difficult to hear what the patient's body and mind are saying. I have tried to put this rather crudely as divesting our minds of memory and desire so that the noise made by our learning, our training, our past experience, is at a minimum. In that way you get as wide a view as possible. Then you can begin to hear or feel something which, if it were an inflammation, would cause you to narrow down your view to the site of the infection so that you could look at this spot which is painful. If your patient will allow you to see him often enough, if he will allow you to remain silent, if he will allow you to be ignorant, then you may be able to see what this painful spot is – whether it is in the mind or the body.

In saying all that, I am talking about matters which have not yet been discovered; nobody can help you there except you and your patient between you tomorrow. A physician would have to dare to say, "I shall want to see you tomorrow; I don't know what is the matter, but I think it *may* be going to be an appendicitis, or it may be nothing in particular." The analyst can observe the body, the appearance

of the patient, *and* can observe what appears to be a symptom or a sign that the patient has a mind. The capacity for articulate speech can be observed, can be searched, can be looked at so that it might yield evidence of the location of the pain. I suspect that sometimes a physical pain – say, below the diaphragm – can seep its way up to the mind so that the symptom, the sign, which is not so obvious in the body can be observed in the mind. Then the analyst may be able to make an interpretation which a physician cannot make because he hasn't learnt how to observe the mind.

As I have said, the occupation of psychoanalysis is a dangerous one, but the analyst cannot deal with that dangerous situation by running away from it. We all know that; we all know it would be no good getting up and leaving the room. What is not quite so easy to see is that we can become *absent in mind* if we don't like what the patient is saying. In my experience, the borderline psychotic patient – so-called – always knows when the analyst has become absent in mind. Sometimes the patient will say, "You have gone away", and it is easy enough to give an interpretation such as, "Ah yes, you are aware that it is coming up to the week-end break – I shan't see you tomorrow or the day after." It is a rational explanation – and in analysis rational explanations are so common that there is no shortage. We can produce interpretations, clothe ourselves with interpretations which hide our nakedness. Not so with the borderline psychotic. The problem is, are you going to interpret the patient's statement as his reaction to the week-end break or the termination of analysis? Or are you going to interpret, "You are feeling that I am not really paying attention"? This is the penalty which the analyst pays for being an analyst – he is under constant observation. Unless we are aware of that, we don't know why we get so tired.

A greedy patient can behave in such a way that when his hour is over, you are so bothered about what he will get up to next that you take up the next patient's time in thinking about the previous patient. I think it is as well to be clear about this: that you will try to prevent the patient, say, from throwing himself out of the window while he is in your consulting-room during that hour. After that you can say that you will not be responsible: somebody will have to bring the patient to your office, and somebody will have to take that patient away – whether it is a child or an adult, psychotic or non-psychotic. Otherwise, the other patients during the day are cheated; the

attention which the analyst ought to be devoting to the observation of all his patients is spent on thought about what this one patient will do. You cannot work twenty-four hours a day: only you can say how many hours you can work, only you can arrange the conditions so that, during those hours, the conditions enable you to work because your attention is not distracted by matters that take you away from the job in hand.

Let me remind you again that this is why I think it is important to be able to denude your mind either of what you know about the past or of your desires for the future. The whole of psychoanalysis seems to me to be shot through with a certain optimism – these ideas of "cure", that there's a good time coming. What do we know about what is coming? What do we know about this universe in which we live? It is possible that the patient needs to be stronger and more disciplined in order to be ready for whatever happens – not just prepared for heaven, a cure which is heaven-on-earth.

One idea we can pursue is that of the truth. You can feel that a painter is a good painter if his painting is an attempt to show you what is true – the Impressionists didn't paint in order to make things more difficult to see. You can feel the difference between a musical composition which is an imitation of the truth and another which is a formulation of the truth. In analysis we have to forget whether the interpretation is the right interpretation, or the Kleinian interpretation, or the Freudian interpretation – it is all irrelevant. The only relevant thing is whether it is a *true* interpretation. This is illustrated with dramatic force if you are asked to see a patient who is in the terminal stages of disease. The doctor can expect the analyst to tell the patient reassuring stories: the analyst has to resist that pressure. I don't think such a patient is misled about his condition – although it is possible, because we are all so used to believing nonsense of one sort or another, of being told reassuring stories. A patient will sometimes say, "I don't know what you mean" – he doesn't believe that the analyst is in any way different from everybody else. He thinks it very unlikely that the analyst will say just what he means. But the analyst has to get so accustomed to saying what he means that he does so *always* – however unpleasant it may be. He cannot think, "Ah yes, X is the right interpretation, but I will say something nicer." He must ask himself, "What language shall I talk to the patient so that he can understand what I say?"

It is possible to feel that in certain patients, ideas, thoughts and feelings are prompted from a basic physical level – for example, prompted by the adrenals or by the gonads. Can the impulse, thought or feeling that comes up from a physical source affect the mind and thoughts of the patient? Can that same mind be told something in language which can track its way back again to these primitive, fundamental levels?

I had a patient who submitted to surgery for a heart condition. Whether the operation was really carried out or simply an incision made on the skin, I don't know. For all I know, it may have been a psychological incision. But I do know that the operation was not successful. I had to draw the patient's attention to the fact that there must be some reason why he kept coming to me when his heart had been operated on – or so he told me – and that he must know that all I ever did was talk. Yet that patient, who hadn't dared to travel, began to do so. *I* hadn't operated on his heart and I don't know what happened to my interpretations once I had given them. The impression I got was that the patient did listen to what I said – but what happened from his ears to his mind I don't know.

These are problems which we may be able to solve if people come to see us; you may gradually feel – tomorrow, the day after – that there is some evidence which begins to formulate itself in the same way that an obscurity on an X-ray film shows you a pattern. If you know what the skeleton of the chest ought to look like, then you can see on an X-ray film that there is an area of opacity; where a photograph of the skeleton ought to emerge, there is a misty patch. So getting back – or forward – to tomorrow's patient, I suggest this view where you are vulnerable to anything that your senses will tell you: as you watch, you begin to narrow it down, and then ask yourself why you are acting in that way. That depends on daring to feel or think whatever you feel or think. I have spoken of it before as a situation in which all sorts of thoughts are flying around – the patient gets rid of all his thoughts which then, in my pictorial imagination, are flying around. If you can be wide open, then I think there is a chance that you might catch some of those wild thoughts. And if you allow them to lodge in your mind, however ridiculous, however stupid, however fantastic, then there may be a chance of having a look at them. That is a matter of daring to have such thoughts – never mind whether you

are supposed to have them or not – and keeping them long enough to be able to formulate what they are.

Q: I wondered what space we should be looking into: might it perhaps be a mental space that can also gradually be built up? And, then, what might a space for looking inside ourselves be worth?

Bion: Projective geometry is implicit in Euclidean geometry, but it took a very long time before Descartes was able to formulate the Cartesian co-ordinates. Then, released from the pictorial image of lines, circles, points, it could be formulated in terms which were not visible. It is possible to formulate things like conic sections mentally – and not only the lines, but the *direction* of the lines: vectors.

What about these thoughts that float up, shall we say, from the adrenals? Could we discover some kind of coordinate system by which it would be possible to observe them going in the other direction? To take my pictorial example of a hand, one side being psychosomatic, the other soma-psychotic: if you can give an interpretation about a psychosomatic condition, could you also give an interpretation in such a way that it would be soma-psychotic? In that way, these puzzling things like schizophrenias, manic-depressives and so on could become much more comprehensible. Consider "manic-depressive": manic husband marries depressive wife, and they thus give birth to a *folie à deux*. Could we put it in the other direction? Start at the *folie à deux* and end up with two people? And would they remain married?

Q: There is some confusion here in the translation: are we, in fact, talking about "soma-psychotic", or should it be "soma-psychic"?

Bion: They are different views of the same thing – it is a sort of diaphragm, a caesura, the "impressive caesura of birth". There are plenty of impressive caesuras of the birth of ideas, and each time somebody has a new idea – for example, psychoanalysis – it at once becomes a barrier, something which is difficult to penetrate. Instead of being liberating, it becomes imprisoning. So even while we try to formulate an idea which would be liberating, we formulate yet another caesura which is liable to become impenetrable.

Seminar 5

15 July 1977

I don't know "us", and I don't think that we know "us" either, because we – whoever we are – have not met before. We are none of us who we were even an hour ago, so I shall start by having a speculative imagination, something that is *not* a fact, an imaginary fact. When there are a lot of individuals here, there are also a lot of thoughts without a thinker, and these thoughts-without-a-thinker are floating around somewhere. I suggest that they are looking for a thinker. I hope that some of you will be prepared to allow them a lodgement in your minds or personalities. I realize that that is asking a lot, because these thoughts-without-a-thinker, these stray thoughts, are liable also to be wild thoughts. And nobody likes giving a home to wild thoughts which are then said to be *your* thoughts. We all like our thoughts to be domesticated; we like them to be civilized thoughts, well-trained, rational thoughts. All the same, however wild, however irrational, these thoughts may be, I hope that you will dare to give them a temporary lodgement and that you will then provide them with a suitable verbal costume so that they can express themselves publicly and be given an airing even if they do not appear to be very well fitted out. I hope that these speculative imaginations will have a chance of achieving a certain degree of respectability, so that they can exist even in a scientific community. Like speculative reasons, they are feeble creatures, easily destroyed.

I find from time to time a patient who says that he is incapable of imagination. In such circumstances I am not surprised if that same person complains of insomnia. Such people are afraid that they will be off their guard as they are when they go to sleep. When they *are* able to go to sleep and to have dreams, they say they have had a dream because a dream is relatively respectable; we are permitted

to have dreams. It is not regarded as quite so respectable to have an hallucination or a delusion, although sometimes the society or group or the culture allows people to have daydreams. Usually an attempt is made to make these daydreams respectable by excusing them as a poem, or an impressionist painting or a modern musical composition. But that again depends on daring to have a wild thought, whether awake or asleep. And it depends on being able to wake up, to be fully conscious, to have all your wits about you, and then to be able to transform the wild thought or the wild image so that it becomes relatively respectable, so that you can say, "It's a field of poppies."

Sometimes such people are forgiven, especially if they are dead. Then you can say, "After all, it was Giotto, or Leonardo." People like that can be excused if they drew a line around their wild thought and called it "God", or "The Virgin Mary", or "Saint Anne". But most of us hardly dare to hope that we shall be able to make that excuse for our wild thoughts, wild images, wild music or wild paintings. So when I say to you, "I think somebody else ought to do some talking, however wild the thought, however irrational, however unaccepted or unacceptable or unthinkable to the group or person", I am really expecting you to be courageous. That point is difficult to see, because apparently and factually the circumstances are quite comfortable; it sounds and looks and feels as if it is safe to say what you think.

I try to speak the truth to my patients and to dare to say what I think, even though I have to modify it slightly because I want them to understand what I have said. Sometimes the patient will say, "I don't know what you mean." This may be because I am not good at expressing myself in articulate speech, but often it is because the patient is not used to hearing somebody say what he means. So here you run the risk of being regarded as responsible for your wild thoughts, and then you run the risk that somebody will say, "That person is a trouble-maker."

If I now fall silent, it is in the hope that you will be able to hear yourselves think, however wild the thought is, even to yourself. There is always one person who can hear what you think – and that is you. [*Long silence.*] You can hear the clamour yourselves. The group seems to me to be suffering from insomnia.

Q: In a report I read about life in Persia today, the journalist said that the principle followed by most of the population is that everyone

> is the slave of what he has said and master of the words he has not said. Now it seems to me that the opposite may also be the case – that is, that a person is the master, the owner, of what he has said and may, in fact, be the slave or prisoner of what he doesn't say. In such a situation, it seems to me that if someone thinks something, there may be someone who does not think or whose thinking is confused; at least he has a path of his own to follow. Alternatively, there is the situation of someone who thinks but doesn't express what he thinks. That puts me in mind of a pregnancy in which the foetus is likely to die if it is born too soon, because it is too weak and not fit to live. In the same way, if a thought is not expressed, if it is immature, it will not survive; it won't go very far. But if the foetus stays in the mother's body for too long, it will die inside, just as a thought will die in the throat if it is held back for too long.

Bion: The idea has been expressed, as I said the other day, by a previous inhabitant of this city, Horace [see Seminar 2]. Think of the first people who started to communicate with grunts and then dared to invent articulate speech; they had to be their own poets. You have to dare to be an artist; somebody has to dare to write graffiti on the walls of the cave. What those artists were called, I don't know. They were not called "Homer" or "Leonardo", and yet their terrifying dreams are there on the walls of the cave. Their terrifying sculptures are visible in the caves of Elephanta. The first attempts must have been very crude. What about the graffiti now, the drawings which appear on the walls of Rome? In the Lascaux caves I have seen the uneven surface of the wall used to produce an effect of perspective; that sculpture has been achieved by a collaboration between a human character, personality, and the forces of nature; the earth bulges out in a certain place and the artist uses that as a part of his sculpture.

But never mind the past; we can do nothing about that. What we can do something about is the present. Faced with a choice, you always choose both what to do *and* what not to do. I can choose to do that, and I can choose to do that, meaning "I choose this, not that".

Here, now, dare you express your creation, make it public – at any rate to yourself, because you are bound to hear? Somebody once collected the bits of paper left after a meeting of important statesmen;

their scribbles on pieces of paper would not have been accepted by a museum of modern art. If you decide to remain silent, then you are also deciding not to say what you could have said; you are bound to regret not having spoken up, and you are bound to regret having been so foolish as to have said what you were thinking.

Q: I'd like to put to Dr Bion an attempt of mine to use speculative imagination. In so far as a cell membrane separates an inside from an outside and selects the distribution of the cellular substances into two parts of the space, we can say that the membrane sends a remote message and organizes the space in a more complex way than would be possible if the molecules were scattered at random. As the complexity of the functional aggregation (an organ, for example) increases, so too do the interdependences and complexity of the relations that must be maintained between the inside of the organ and other regions of the organism. For example, the adrenal gland will be separated from a surrounding space by a sheath, but this sheath will have lost the property of maintaining functional relations with the outside, as the cell membrane did. The function of an organizer capable of acting at a distance will now be assumed by the system of adrenal secretions and specific receptors for these substances, which are located outside the adrenal gland (in the pituitary, say). In other words, new membranes are created to regulate exchanges, and these are no longer located at a single point in space and do not act by contiguity. So in effect we have membrane systems capable of acting at greater distances with less transport of substances.

My question is this: Considering these examples, do you think it useful to see evolution as a series of functional leaps that tend to preserve homoeostasis in a system whose growing complexity gives rise to ever-increasing dishomogeneity between the various regions of the space and, for this purpose, needs regulating systems capable of acting over greater and greater distances? Do you feel that this can throw any light on the fact that the senses are a membrane capable of acting at a greater distance between two inhomogeneous entities such as the body and the external environment, by forging a relationship between substances originating in the systems that act at short distances (hormonal stimuli or emotions) and receptors in the far-off mind of the mother?

> Could it be that the birth of thought here serves as a membrane that can actually interpose itself for action at a distance between individual substances and social receptor systems?

Bion: The physiologists – I don't know with what degree of accuracy – describe the relationship of the cell to the extracellular fluid, which is as near to unpolluted water as you are ever likely to get. This makes it easier for me to reply to a part of what the previous speaker said. I can imagine – again, a speculative imagination – that, living in a watery fluid, a potentially highly gifted creature, an embryo, would not be able to tolerate what its primordial senses tell it. For example, it might hate the noise of the blood rushing through its embryonic body.

For the sake of simplicity I will mention an exaggerated case which nevertheless is factual – as far as I know. The mother, while pregnant, was subjected to a terrifying experience. What changes in pressure occurred in the amniotic fluid, I can only guess. And what those changes in pressure would be perceived as by the optic and auditory pits, I don't know. I am still postulating the possibility that the embryo, which has all the mental and physical makings, can be precociously, prematurely subjected to an experience which it cannot tolerate. The actual experience that I am acquainted with was that of a patient of mine who had severe symptoms. When he was a full-term foetus, a man entered the bedroom. He murdered the father, the mother, and three children and precipitated the premature birth of this full-term foetus. The child grew up and knew . . . well, what? I don't know. But everybody agreed that the child knew nothing about it, that it was not told, never had been told of this terrifying event. When I knew the patient, he was disapproved of by everybody, including the foster-parents. The patient had no dreams. After being subjected to the analytic experience with me, he became – and everybody was in agreement – infinitely worse. He had terrifying dreams; he was delinquent; he hated any man or woman that he had to deal with; he threatened murder and suicide. Naturally he was removed from the bad influence of the analyst; obviously analysis was doing the wrong thing and so was the analyst. So I could do nothing more. But the patient, when he was of age, came back to me. He didn't know what he wanted, but he knew he wanted me. That seems to be a situation in which the person, even before birth, is prematurely subjected to a stress which he cannot stand.

I have had other, less dramatic experiences in the analysis of patients who had been psychiatrically diagnosed as schizophrenic and borderline psychotic. I have three examples in mind: the root trouble appeared to me to be the great intelligence of all three people. I couldn't very well pass on the fact that, to me at any rate, they were highly intelligent people, but it was possible in two instances to draw the patients' attention to vestiges of acute observation – so acute that they could not stand the information that their primordial senses brought them.

There is one fundamental experience which I can put in this way: the patient is aware of two very unpleasant experiences – being dependent on something not himself *and* being all alone – both at the same time. That seems to me to be something which can happen even before birth when the patient is, as it were, aware of his dependence on a watery fluid and his inability to tolerate being all alone.

Ordinarily we are able to continue to operate our sense of smell by taking the watery fluid with us after birth, after entering into a gaseous fluid; the watery secretion of our nostrils enables us still to be able to smell, even in a gaseous medium. Sometimes there is too much watery fluid; we complain that we cannot breathe, we have catarrh – what is potentially an asset becomes a liability. Similarly, the patient cannot stand the load of intelligence he has to carry; he does his best to get rid of it. After the "impressive caesura", he still remains highly intelligent but learns it all again. That highly intelligent person *appears* to be very intelligent and to know and to learn easily everything that he is taught. The only trouble is that he can be extremely intelligent but not wise.

Note that I have to make a distinction between "intelligence" and "wisdom". I would hate to try to define either, but here in this group I can fall back on your assistance in grasping what I mean in spite of the inadequate articulate communication I make. You can use your own wisdom to decide for yourselves how wise you or anyone else would be to rely on the wisdom of a group. Sometimes you may find yourself in a culture which is highly intelligent but not wise; you can make up your own minds about the extent to which you would regard such a distinction illuminating in clarifying your own impressions of the group in which you find yourself. In that very activity, you add a dimension to your self; you exercise and develop

your capacity for discrimination. You can rely on a certain amount of experience – possibly hearsay, possibly direct experience – which you yourself have had, to assess the nature or characteristics of the society of which we are members.

Are the inhabitants of this geographical space wiser than they were in the time of Homer, Horace or Virgil? Of course, we don't know because we cannot say what Rome was like when those poets existed. But you can have an idea whether or not *you* are wiser than you were when this meeting started. And on your answer to that question will depend whether you go on meeting together or not. That depends on daring to discriminate. How do you measure the distance between these two points – now, and the beginning of this meeting? Or the distance between Horace's Rome and today's Rome? In kilometres, hours, weeks, days? Or will somebody have to invent a system of coordinates by which we could place ourselves in mental time and space?

Those capable of mathematical thought seem to have done something about it. Euclid's geometry didn't solve the problem of parallel lines satisfactorily, but geometry, as we know it now, was *implicit* in Euclid's geometry. It took a few hundred years to become *explicit*. That depended on a growth of experience by the Hindus with their decimal system, and Descartes with his Cartesian co-ordinates in which the limitations, the confines, the restrictions of Euclidean geometry could be transcended by algebraic geometry. We are no longer dependent on our eyes or even on what Milton called "inward eyes". In that way we can suppose the line that joins two points, both of which are imaginary. So I say, *dare* to use your speculative imagination, whether your culture likes it or not.

We know about the function of the adrenal glands – something which we could say is not thought at all but chemistry, biochemistry. When and how does it become possible for the individual to be able either to fight or to run away? When shall we become capable of running away from, or fighting for, the freedom to think? I have interviewed plenty of people who could not get over the fact that they had had to surrender in war and were taken prisoner. I have had good reason to mourn those who, in a hopeless situation, sacrificed their lives rather than surrender. "He who fights and runs away, lives to fight another day." But how much time have you to make up your mind? Here we can debate the problem for an hour, two hours; in real

life there is not time for debate: you have to decide instantaneously whether to translate yourself into action which is apparent and clear, or whether to preserve it for another day. That is why, in producing a framework suitable for learning, there must be ample opportunity for making decisions. To put it in visual terms, one must provide a child with the space necessary for development. This applies to us also – any decision that we make, any statement that we make, should leave room for growth and development. In talking like this, I am actually producing a system, an architectonic, of my own thought. But that very fact also involves secreting a kind of calcification – I borrow the term from physiology, where we say that the arteries become hardened. We have to be aware of something similar happening with our thoughts: we become wedded to a state of mind which is serviceable, may even serve us well, and we don't want to have it disturbed. The advantage of a group of people coming together is that it is like seeing various aspects of our own personality all at the same time. Can you detect the calcification in this group? Can you detect it in yourself?

Q: I'd like to ask Dr Bion a question. Is it possible to identify any kind of relationship between the factor he has described as intelligence and wisdom and the entities he calls Ps and D?

Bion: A person can often rid himself of a disturbing tendency to initiate *anything* – he prefers the depression to the state of mania. Sometimes, when the person has rid himself – at whatever stage in his life – of the unpleasant experience of constant changes from depression to jubilation, from jubilation to depression, by becoming permanently depressed or remaining in a permanent state of mania – to put it in the exaggerated form – such a person will attempt to deal with it by finding a partner who will be depressed instead of him, or who will be manic instead of him. Someone who doesn't allow himself to be too acutely observant may say, "What a happy marriage!" If you allow yourself to be more acute, you might say, "No, not a happy marriage – a *folie à deux*". There are various versions of what is basically the same thing; it depends on the extent to which you allow yourself to be sensitive to the *implicit* facts. Geometry does not change – projective algebraic geometry is implicit in Euclid's geometry and became explicit later. What is the origin of this culture? When was it implicit, and what was it implicit in? The civilization

of Valerian? The civilization of Hadrian? And what civilization will be shortly occupying this space? I say "shortly" because the scale of measurement with which we are concerned is not the span of a human life – a few hundred years is nothing. What is the culture implicit in this meeting? What will it look like when it becomes explicit?

Q: Let my try to suggest some answers, or at least to reformulate some of the questions. Well, I don't know what I shall say in a little while, but I imagine I can rely on the support of the group while I speak. My feeling is that there were two simultaneous stories, at least as I experienced them. One of them had to do with me directly, as someone who was very worried in a situation of blockage, embarrassment, respect and concern, and the other was more connected with the group. One of the impressions this gave me was of a sense of rebellion stronger than my own, which I perhaps felt as a part of myself, but it also had a lot to do with our being psychoanalysts or, alternatively, with our being people meeting each other. There was something else too. On the one hand, I felt that I didn't agree with the ideas Dr Bion was putting forward about thinking, while on the other, perhaps I did.

In other words, the feeling I normally have when speaking in a group is not that I am speaking myself, but that, at the very moment when I have noticed that the group is spatialized, just as my mind is spatialized, I can speak as one of the focal points of a multidimensional conversation. On the other hand, I recognized that what Dr Bion said about the patient whose father and mother had died – had actually been murdered, leaving him alone and dependent – applied not only to me but perhaps also to other people in so far as they were not in an all-embracing group situation. Let me say just one more thing, and then I won't take up any more of your time: it's that I felt that if I had suggested creating an atmosphere – for instance, a damp atmosphere – then either I would have felt like getting drunk, having a drink together with other people, or . . . well, I'm also told that an analyst can't drink.

Bion: To fall back on a physiological model: if an embolus forms in the circulatory system, it may lead to the death of the part of the body which is dependent for its supply of blood on a particular arterial system. Alternatively, a collateral circulation is formed. If this group, for example, prevented the development of thought and

mental growth, then I think it would die. I have no difficulty in believing that in certain societies analysis will not survive, but there may be other societies in which a collateral circulation can be set up. Put in more general terms, I don't see any reason why the human race should survive; the function of life could be taken up by an entirely different form of animate object – like viruses, or bacteria, or bacillae. In some respects our inherited simian characteristics can be far more active and virulent than what we regard as our "human" characteristics. Our simian intelligence may be so clever at inventing tricks that it could invent an atomic bomb – only better. That would solve the problem long before we had the wisdom to know how to use our capacity for nuclear fission. At present we try to forbid the import or export of nuclear submarines and so on, but none of our statesmen would bother to prohibit the export of intelligence – and still less would they be bothered about wisdom.

We will have to have a pause for thought – I take it that our bodies have to have a certain amount of rest. So I suggest that we adjourn for our terrifying dreams or happy visions, according to taste.

Seminar 6

16 July 1977 – Morning

Q: Last night Dr Bion asked us to express our wild thoughts and, at the same time, warned us not to express them too respectably. Then he made an interesting point about the difference between intelligence and wisdom, specifically as regards groups. I'd like to ask Dr Bion if putting one's wild thoughts into respectable form might not be equivalent to intelligence, as opposed to wisdom – in other words, a particularly well-masked form of destructiveness.

Bion: It is much more difficult to reply to that question when it applies to one's own thoughts at the time. There is no way of avoiding the fundamental fact that one is always dependent and alone. When I use those words, I am using relatively highly developed articulate speech about something which is basic, fundamental and has to be experienced. Even the infant has to be able to solve that problem; it does not like the feeling of dependence or the feeling of loneliness, isolation – nor do any of us. I can practise my speculative imagination and say that the infant feels that it may express its feeling of isolation by crying, supposedly for assistance from whatever it is dependent on – the breast, the mother, the parents. Both the infant and the parent have this same problem. The child one suspects of being psychotic or borderline psychotic can be so terrified of its feelings that it expresses them by crying for help, constantly, tirelessly. But the parents do tire; their problem is whether to nurse that infant or whether to escape from the sleepless situation. So when an individual – as, for example, here – knows that he has something to say, the question is whether to say it or not, because he is afraid of discovering either that there is no one to hear or that there *is* somebody to hear but that somebody will run away. Thus the dreaded isolation is made worse, not less.

We can turn the present situation to good account by trying to decide whether to say, to express, what we have to say, or not. That may not matter very much to us here, but tomorrow the group or the culture may not be so friendly. Here you can practise expressing whatever you are capable of expressing – your distress, your happiness, your capacity – and dependent on that experience is what you express tomorrow, in much the same way as the infant's capacity to express what it feels depends on the experience that it has at its first attempt.

Practising your speculative imagination, consider this: does the infant initiate birth by trying to break out of an intolerable situation, the mother's womb or the amniotic fluid? If so, it could then feel responsible for initiating the expression of its own experience, responsible for making obvious its own existence. In today's complex situation where there is so much evidence, can we still detect vestiges, very active vestiges, of our anxiety, of our fear to express whatever it is that we are capable of? We can be afraid of expressing our stray thoughts, wherever they come from, because we are afraid of the reception they will get. And then the poet, the painter, the musician implicit in each of us does not get expressed, for fear it would be destroyed if it were.

Winnicott was once asked, "Why is the good object destroyed?" The "good object" is only a technical psychoanalytic term – I don't feel particularly impressed by the question or the problem. But I do suggest that we have a chance of seeing not *why* the good object is in danger, but that destructiveness is stimulated by the presence of something which can be destroyed. In other words, there is a primitive pleasure to be gained by the exercise of cruelty and the destruction of something which is worth destroying. In so far as we are capable of being parents, we are also vulnerable to the forces which would destroy what the creative or potentially creative parents could create. We have to become used to finding ourselves members of this particular group or culture, but we cannot get used to it unless we dare to exist in it.

Q: I thought the image with which Dr Bion began his presentation last night was very beautiful: one quite expected to see wild thoughts floating around in the room. But afterwards I wondered whether these thoughts were an emanation of the Holy Spirit, and, if not,

what is Dr Bion saying? I then expected a solution to the mystery of the beginning of St John's Gospel, which would tell us where the Word was and help us to understand how it had been made flesh. But none of the rest of what was said helped me with this, and, in particular, the long discussion of man's difficult acquisition of language, starting from grunts, confused me. I felt that this beginning was contradictory: in a word, does God – or whoever – grunt, or does He speak?

Q: I thought I would tell Dr Bion that I felt the group had uttered a wild thought by bringing this previously expressed wish . . . I also thought that our discussion was, in a way, a manifestation of longing, and, provided that Dr Bion is prepared to tolerate this insistence on language, I wanted to return to the subject of music . . .

[*Interruption due to external noise*]

Bion: I can't answer that question, but you can see the answer for yourself: either I can cover my ears so I can't hear so much noise and won't have to listen to your questions, or I can get up and leave the room. In fact, with my amount of experience, I am quite capable of being deaf and blind to what I don't want to hear and see without either covering my ears or shutting my eyes. I am also capable of being geographically mobile – in fact, I shall leave Rome shortly. But I don't propose to try to take the place of your own ability; I don't propose to tell you why I leave the room, or why I am deaf and blind to what is said to me, because my answer would be prejudiced – in so far as I know it at all. You are free to use your capacity for discrimination and think what you like about my reaction. I know that it will be disappointing because I know by this time that I am only human, and I shall therefore probably do what any other human being would do. When somebody is able to make an apocalyptic statement, like the Revelations of St John, it depends on whether anybody would be prepared to hear when the individual is able to transform his thoughts and feelings into verbal expression. Milton says, "Hail, holy light . . . may I express thee unblamed?" At the end of this passage from the commencement of the third book of *Paradise Lost*, he says,

> . . . from the cheerful ways of men
> Cut off, and, for the book of knowledge fair,
> Presented with a universal blank

> Of nature's works, to me expunged and rased,
> And wisdom at one entrance quite shut out.
> So much the rather thou, Celestial Light,
> Shine inward, and the mind through all her powers
> Irradiate; there plant eyes; all mist from thence
> Purge and disperse, that I may see and tell
> Of things invisible to mortal sight.

In the Revelations, St John states it in terms of a light which is expressed verbally, but he *himself* expresses it verbally. Can we listen to that verbal expression? And can we further regard or tolerate the meaning which lies beyond the verbal expression?

In the *Bhagavad Gita*, Krishna expresses doubts that Arjuna would be able to tolerate the spectacle if he were to reveal himself. In other words, it depends on the meaning which lies beyond the apocalyptic revelation. There are certain gifted people who are able to dare to express what it is that they can hear or see: "In the beginning was the Word"; "Let there be light"; "Won from the void and formless infinite."

A mathematician might try to express "infinity"; a religious person might try to express the Godhead (not God, but "the Godhead"); a scientist might try to locate the source of light (Newton attempted to do so by his work on optics); Leonardo could draw a picture and say, "This is what I see"; Giotto could say, "This is what I can see." But none of them can *make* us look or listen to what is shown or said. We can be as blind, as deaf, as insensible to the composer, the painter, the dramatist who is either in ourselves or outside. Here we don't have to pay any attention to anybody – not even to ourselves or to anybody who is "not self". The advantage of coming together is that we have a chance of making our own choice. As Shakespeare puts it, "To be, or not to be, that is the question". He doesn't say what the answer is; he says, "Whether it is nobler in the mind to suffer the slings and arrows of outrageous fortune, or to take arms against a sea of troubles, and by opposing end them?" That is a choice nobody can make for the individual – except the individual. Only he can decide whether to be or not to be.

Q: We were talking about thoughts without a thinker. Let me tell you about something that I personally found very striking, which I cannot explain rationally to this day. Perhaps, in the end, it will all

turn out to be much simpler than I imagine. At any rate, at about 11 o'clock on Wednesday morning I received some very sad and distressing news. On the same day, a patient began his session by saying that he felt that I was in great pain. So far, I must say I was not surprised, but then he brought a dream he had had on the Tuesday night. Putting together the dream and the associations, it was clear that they amounted to a perfect description of the event that had made me so sad. When I met Dr Bion last week, I had already been wondering whether a situation like this could be called communication.

Bion: So much seems to depend on our pre-existing classifications. That is why I say that, in the actual practice of analysis, in real life – as opposed to the theories about what life is or what analysis is – you can compare the facts. Either there is something wrong with science if it does not allow room for the growth of the human spirit or mind, or we have to reconsider what we regard as "facts". What is a psychoanalyst? It appears to me that Freud aspired to a scientific standard according to his ideas of what science was at that time. I don't think that his system really made room even for his own development. After all, the quotation, "There is much more continuity between intra-uterine life and earliest infancy than the impressive caesura of birth would have us believe", is from 1936,[1] near the end of his life.

What happens if somebody allows himself to have an experience such as the one we have just had verbalized for us here? It seems to me that the analyst who actually participates in the experience has a chance of deciding whether to try to communicate – as he is doing here – and whether we would be capable of hearing and understanding the communication. If he is to communicate the experience, which language is he to talk? Will articulate speech do? Or would he have to be a musician, a composer, or would he have to paint it? In any case it requires courage if he is going to dare to make public, to communicate to somebody not himself, his experience. It may take a long time, either in the individual's life – which is, after all, pretty short – or in the life of the group. This sad event, this experience

[1][This is a mistake. The quoted phrase is in fact from Freud (1926d [1925]), p. 138, though there was a New York version with the publication date 1936. *Ed.*]

of sadness – where did it originate? Could it be located in some geographical place? Or could it originate in the mind of the analyst? Or could it originate in the relationship between two people? Let me take refuge in the relatively reasonable explanation and say it originates in the relationship between these two people – you can see how *rational* that would be, how in accordance with theories of transference and countertransference and so forth. But suppose we are not satisfied with that explanation. Perhaps we should then have to extend our ideas of what is science or our knowledge of the central nervous system and our capacity for receiving information via our peripheral and central nervous system. We can all be aware of the information brought to us by our "senses" – in the neurological sense – by the stimulation of our nerve endings. But the questions that have been raised here may mean that we have to become aware of the possibility that there are other receptor organs of which we are not aware. A physician, who only purports to be concerned with the body, can fall back on what his senses tell him; he can take precautions to be sensitive to the universe in which he lives. But then he also has to be able to tolerate that information and to try to understand what it means. The same thing applies to the apocalyptic vision which to some extent can be communicated to us by the greatest of our predecessors, like Leonardo, Giotto, Newton, Milton. But first of all we have to look at what they show us – and most people don't – and then, while we are looking, allow ourselves to recognize the meaning which lies beyond. It is easy to dismiss St John on the grounds that he was . . . well, one of these "queer" people. It is easy to dismiss this particular patient as a psychotic or a borderline psychotic. But what are you to do when there are two people involved – yourself and this supposedly borderline psychotic? You can hear what these two people say to each other, and you can be aware that you are not satisfied, that there is something that you do not know.

Q: When Dr Bion talks about this wild thought that is in some way waiting for us to express it, I feel that he is talking about an infantile experience, such as when a very young baby experiences the emotion of coming upon a thought of its own as a foreign body. I'd like to know his opinion on three different situations. First of all, when does each of us as an individual come into contact with his own thoughts, and how does this mating with one's own wild

thought come about? Second – and this is perhaps even more interesting – how does the mating with these thoughts come about in the dyadic analytic situation?

It seems to me that in a relationship between two people, there is actually a whole crowd of characters on both sides, and so I ask myself who is thinking, why they are thinking and how these thoughts meet. There seem to be a multitude of people with wild thoughts flying back and forth all the time. But what happens in the group situation when the individual, faced with the encounter with his own thoughts, is much more alone and, in a way, much more fragmented than in the dyadic situation? In the dyadic situation of analysis, one seems to be several different people. In the group situation, what happens is like a kind of fragmentation and delegation of something of oneself to another person, to make the encounter with the wild thought less dramatic. To sum up, how is the Word made flesh in the individual, in the dyadic situation, and, on another level, in the multitude represented by the group?

Bion: We come across this situation at a very late stage. We are so educated that it is practically impossible ever to get to wisdom. We can start by learning the alphabet – a, b, c ; it is stupid and it's dull. But if we persist we may learn to put it together – c . . . a . . . t – and then somebody might say "cat" and relate it to an actual picture or animal. If this process goes on, we can learn to put words together and discover that sentences have a meaning. In that way we can reach a stage where it is almost impossible to see the words for the alphabet; and finally we cannot detect the meaning for the words. We can be so well educated that it is almost impossible to realize that life may have a meaning. Therefore, some process has to be discovered by which we could forget what we have learned in order to be sensitive to the fundamental thoughts or feelings which may still have survived – there may still be some vestige of wisdom in the human race. I don't want to adhere particularly to either an optimistic or a pessimistic position if I can avoid it, but it is difficult to remain blind to the possibility that we now know so much that we are virtually incapable of being wise. We can look at a sculpture, we can look at the written word, we can read the Revelations of St John – they can mean nothing if we are so clever that we cannot see the meaning of what is pointed out to us. I don't see any alternative to allowing ourselves

to practise, as opposed to theorize; to live instead of theorizing about living. Victor Hugo suggests that the physical world of which we are aware is, indeed, the creation of some God or Spirit. Another of these gifted people said, "The heavens declare the glory of God: and the firmament sheweth his handy-work" [Psalm 19]. Even astronomers are trying to read – not books, but the heavens themselves. Someone else could be engaged in examining this same universe through a microscope. So the group as a whole has a wide view – we can examine this universe in which we find ourselves with a microscope, or a 200-inch reflector, or a radio-telescope. Between the lot of us we might make some small contribution in much the same way as somebody who has contributed to who or what we are today.

At some point, before birth, we can feel, fairly rationally, that we are individuals inside another individual. What the communication is between the environment of the mother's womb and the infant, depends on some sort of contact between the two – whether it be physical or something else. Is the embryo, at the stage of three somites, when the optic and auditory pits are beginning to form, capable of receiving some sort of impression? When is the mother aware of having a character or a person inside her? At a comparatively late stage of pregnancy, I think a mother is aware of the athletic feats of this object inside. Is it something which is going to grow into a violent creature which will attack the body from outside? Or will it turn into a ballet dancer?

These questions can be stimulated now, after this meeting, tomorrow, and so on as long as we exist. We can attempt to read the writings, the monuments which have been bequeathed to us, but there is also the problem of reading the universe which impinges upon us *now* and in which – as I have said – we might just as well be embryos in contact with a gaseous environment. If you are capable of painting, the sooner you learn it the better. If you are capable of composing a musical vocabulary, musical words and sentences, it would be useful to know that. If you are a writer, the sooner you learn a vocabulary and how to use it the better. It is no good learning *my* vocabulary – that might be useful as a transitory phase, a point at which you lodged on the way to discovering your own vocabulary and how to use it. That is why my answers to these questions are of no consequence. That is simply knowledge which then acts as an obstruction to your own discoveries. Similarly, it is quite useful to

know what this culture is, but not if the culture takes the place of where you are. The space which you occupy cannot be occupied by somebody else without sacrifice of yourself.

Q: This comment is directed more to the other people in the group than to Dr Bion. It seems to me that Dr Bion is suggesting not that we should perfect our learning, but, perhaps, that we should partake of a creative moment, rather like partaking of Raphael's creativity when he contemplated the Mona Lisa (sorry!). The Mona Lisa will never give us an answer to the problems of our personal existence, let alone our scientific existence, and yet I think that by reflecting on the ambiguity of the Mona Lisa, we might be in a slightly better position to accept our personal difficulties and see them in a clearer light. Our setting in this seminar is perhaps ambiguous because we have probably all read Bion and learnt how much attention he pays to questions.

It is my mistake if I come here expecting Bion to be able to answer the questions he has raised in his books. Perhaps the truth of the matter is that, in this personal contact with Dr Bion, we see only the confirmation that acceptance of the questioning within ourselves is the only way to stimulate the very painful process represented by our personal creativity.

Bion: I think it is what psychoanalysts are trying to express when they talk about a "transference relationship" – that is to say, that we have these preconceptions that there is some sort of authority, a father or a mother, who knows the answer. The aim in analysis is to make that point clear, not so that you can go on feeling how important that person is for the rest of your existence, but because you can then discard it and make room for whatever ideas you might want to express yourself. In the meantime, the analyst can appear to occupy a more and more important position, but it should only be a temporary affair drawing attention to the fact that the analyst is supposed to know this, that or the other thing, just like a father or a mother. The importance of the analyst's position is brought to light so that it can be discarded; the supposed authority becomes redundant, the position of the analyst is no longer useful. This is why it is important to learn, if you can, during the transition stage, who the musician, the painter, the poet is who is struggling to get free from inside you.

Rightly or wrongly we behave as if we think there is such a thing as a mind, a character, a spirit. There are a number of inadequate descriptions – soul, spirit, supersoul, ego, superego, id. They are not very illuminating. But when, in your ordinary life or in your consulting-room, you come across another "something", like the patient who appeared to dream the fact of sadness, then how will you clothe that discovery in words, and what words will you clothe it in?

Seminar 7

16 July 1977 – Afternoon

Bion: Does anyone feel the urge to express an idea or have an idea expressed?

Q: I'd like to ask something: against the background of informal thinking of the last few days, and influenced by what Dr Bion has said at our meetings over the past week, the question of a concept of time occurred to me several times. The way things emerge in the present had seemed to me to be a peculiarity of the group situation, but it also came up, for me, in a dyadic setting – not only as a trick of the trade, but as the only possible way to relate or, rather, to exist. Well, how does Dr Bion see time? Is it a property of space? Is it the act of linking or the conscious link between two or more spaces? Is it the way we perceive our mental space as alive and filled with living objects? . . . How are we to ensure that the concept of relativity that follows from the abolition of definitions does not coincide with stasis?

Bion: It would be interesting to know what has stimulated or caused this particular topic to be initiated. As it has been initiated *here*, it may be possible to form an idea about the source from which this problem has been derived. We can hear the actual person who has asked that question, so we can locate among all of us individuals the particular geographical spot at which this idea of "time" has emerged. We can also feel that we would like to be able to locate the space from which it originated – it would appear to be at a particular spot, which we could describe by giving the name of the person asking the question or by observing whereabouts in the room it seemed to arise. So far, it lies within the capacity of our senses; we can use our eyes and our sense of hearing; and we can use both the binaural capacity and the

binocular capacity to see the point of intersection. Suppose – or, in other words, imagine, use your speculative imagination – that this group has a character. Going on from there and making a further supposition, a further speculation, could the fact that that sort of thought or idea was given expression be regarded as evidence for the existence of the mind or character of the group? Could we compare it with another collection of people? Would they also give evidence of being concerned with this question of time and space? It seems to me that they would, because if I look at today's newspaper, I see a date mentioned on it; it is stated there that in someone's opinion – and it isn't usually disputed – we occupy a particular point in time. If we look at the paper we may also get evidence that someone believes that this is a particular geographical space: if we examine the stone monuments, we get what appears to be evidence that there used to be groups that also thought so at a different time from the present one. So there does seem to be evidence – at least to me – for the existence of a human mind. I wonder if a scientist would be convinced that this was evidence of the existence of a human mind; I could ask him what evidence he had for supposing that there was such a thing as civilized or group behaviour, but it depends on what we consider to be "evidence". We are familiar with people who regard psychoanalysts as being wildly astray in their various theories, hypotheses, but I would like to know what the physical scientist's criterion is and how he considers what *he* regards as evidence for facts as in any way different from what I, for want of anything better, regard as facts myself.

If we watch a group of young children, we see signs of the kind of thing *I* might have thought when I was their age. I can suppose that there was a time when I noticed that things which presented themselves to my senses were not within my reach and I would therefore have to resort to some sort of locomotion to get to them. That would give rise to a feeling which might grow into an idea later, that there was such a thing as time and space which divided me from the object which presented itself to my senses. I could hope to be reminded of almost any state of mind of which I was at some time conscious, and I could use such knowledge or experience as I have to re-assess that evidence for time and space. How much more validity would I be justified in attaching to the evidence for which I depend on this wristwatch – a bit of modern machinery – or how much more value would I attach to a thing which I can see with the aid of a microscope,

or a radio-telescope, or anything between the two? Am I to evaluate my present idea about time and space vis-à-vis the idea of time and space that I would have if I were a hungry baby trying to get at what I regarded as some desirable sweet from which I was separated? "*Le silence éternel de ces espaces infinis m'effraie*" [Pascal, *Pensées*]. I couldn't say that if I were a baby, but I could *feel* it; I could feel that it would be a terrible thing if I had to find the time and the athletic ability to get from here to there. In the meantime, I would be starved for the sensuous satisfaction which I craved to achieve.

If we have minds and need to satisfy our curiosity, we have to find a mode or a scale of measurement. I wonder if that has anything whatever to do with reality, or whether it has much more to do with the ineffectual nature of ourselves. For example, I have read that the distance across the nebula of which the sun is a part, measured through the galactic centre, is estimated as 10^8 million light-years; the space we occupy at the present time, in absolute space, we shall reoccupy again in 10^8 million light-years. I don't know whether anybody here feels any the wiser – I don't. But it sounds terribly knowing and terribly wise. As far as I am concerned it means virtually nothing, except that somebody is feeling better.

On the whole, we fall back on something simpler: we say we meet at four o'clock today, or at a quarter past nine tonight. That will do for our infantile capacity to do a bit of mental crawling.

Q: Between omnipotence and impotence, between dependence and being alone, there are thoughts about power which I don't know how to think.

Bion: That again brings the problem into an area in which it seems we are able to work effectively. That is to say, if we discover that we do not know how to think – although apparently we have the apparatus which might make it possible – then at least we can try to learn how to use such capacity for thought as we *do* have. That still supposes that we have a capacity for thought, that we have a brain, or a CNS, or a sympathetic system which somehow enables us to think. If the supposition were correct, it would be necessary to learn how to use this newly discovered capacity. At present, I think the vast majority of us simply assume that *of course* we can think. And what *I* believe to be thoughts, other people may consider to be nonsense – which is a simple solution of the problem. But when we discover that we do

not know how to think, although we are apparently able to use our CNS and the senses which this makes available to us, the question is, do we know the meaning of what our senses tell us? We assume that we understand the meaning which our senses give us; we do seem to meet together here by using our senses – that is, by being aware of what the information is that they bring us and also understanding the meaning of that information. It is not a particularly profound discovery, but we may have our ambitions stimulated to do a bit more than that. There is something to be said for the idea that if we can cooperate, if we can get so far as to come into the same room at the same time, then perhaps we can collaborate enough to achieve something more than that. We might debate this matter which has been initiated by somebody asking about time and space. And then, if we can collaborate further, we may, by our combined knowledge, make more inroads into our ignorance.

Q: I have a question. One of the pillars of Freud's work is the reality principle, which is also one of the fundamental parameters for assessing analytic work. It also seems to me that most of us, when we refer to reality so as to measure, evaluate and assess it, are as a rule referring to a whole series of spatio-temporal parameters. I also feel that one of the foundations of Bion's thought and work is the reference to truth, so I wonder what use can be made of these spatio-temporal parameters. I'm not saying that there is no reference in Freud to the problem of truth – for example, he mentions it explicitly towards the end of the Schreber case, where he asks whether there is more truth in the scientific mode of expression or in Schreber's way. I myself wonder if there are parameters or coordinates that can help us to feel that we are dealing with truth (beyond the effects – for example, feeling better or feeling worse . . .).

Bion: I think we should resist the temptation, the seduction to believe in our own omnipotence and omniscience. There is plenty of evidence to bring it home to us that we are neither omnipotent nor omniscient – we are not even successful in doing the simplest things. Our reaction to the discovery, so constantly repeated, that we are not omnipotent or omniscient is nearly always to swing over in the opposite direction; the belief in our omnipotence and omniscience is directly built on the foundation of our knowledge that we are

ignorant and incompetent. Let me say the same thing in what may appear to be a different way: our feelings of helplessness, ignorance, incapacity are brought home to us because they are based on the foundation of our omnipotence and omniscience. The more we think we are omnipotent and omniscient, the more certain it is that it is brought home to us that we are nothing of the sort; so we oscillate between one and the other – we are constantly making that journey between A and B.

That might point in the direction of establishing some absolute value in the way that mathematicians do. But this comes nearer to having to invent or create the tools with which to think. While you are attempting to analyse the mind of somebody who is not you, or the relationship between the two minds, you also have to invent or create the very tools you hope to use. Here, we can watch and listen to us trying to learn how to think. That particular space and that particular silence are so penetrating that we get frightened of them. To repeat the quotation from Pascal, "*Le silence éternel de ces espaces infinis m'effraie*"; we are frightened of the penetrating quality of silence. It is not only a matter of being afraid of what we say and think and make audible; it is also fear of what we do *not* say. The musicians have a way of actively symbolizing this with things which they call "rests"; they can record the "rest" as part and parcel of the music. If the orchestra is really in contact with the reality to which it can give expression, then sometimes the cooperation between the various instrumentalists and the conductor will feel different from what it does on other occasions when they are playing the same piece of music. You can say that the orchestra gave a very fine performance of, say, Brahms's Fourth Symphony. What piece of music are we expressing here – "The Collected Works of Freud"? "The History of Philosophy"? "The History of Religion"? We talk about being "psychiatrists" and "psychoanalysts". Are we? Or shall we become so one day?

Wordsworth says, ". . . hearing often-times the still, sad music of humanity" ["Lines Composed a Few Miles Above Tintern Abbey"]. We are supposed to be in contact with our fellow human beings. When you give an interpretation tomorrow, are you sure that it will approximate to expressing the music of humanity or the little bit of it which has got into your consulting-room?

Note that there I have introduced an element of rhythm, timing. Most of us probably have the experience of sometimes feeling that

"that was a good session", when we were really together with one of our patients. We were acting in conformity with a rhythm, even if we couldn't describe it or record it.

Q: Let me suggest something. If we consider the etymology, *pensare* [the Italian for "thinking"] means taking on a weight, *pondus*; the same is true of pondering, in the sense of weighing up – they are all synonymous. *Cogitare*, on the other hand, is interactive with *cogere*, which means "to constrain". So I wonder if a concept of mass and gravity could be introduced into the theory of thought. Thinking would then be tantamount to being compelled to support or lift weights. In that case, one could imagine a kind of gravity applicable to thought, too, which warps its space. My question is this: can we say, "Give me a fulcrum, give me a sign of support, and I will lift up a thought for you"? Also, is the group generally an instrument that is more capable or less capable of acting as a lever for lifting up thoughts?

Bion: The metaphorical use you mention shows that at some time human beings have been aware of this "weight". It crops up now because this use has not been good enough; the question then is whether the group could refine the capacity for thought which has so far been achieved. "*Mene, mene, tekel, upharsin*" [Daniel 5:25] – that was a definite resort to a language which we ordinarily use for describing quantity or weight. The problem today is, are you able to be sufficiently sensitive, either here or in your consulting-room or in your home, to be able to hear the mention of these weights and measures? Could you then consider what they were measuring in that state of mind? If so, then perhaps we could add a dimension to our capacity to think. We may not make much progress, but the fact that we are thinking may strengthen our mental musculature. Could this group think and talk and discuss in such a way that our mental capacity would be able to carry a bigger load at the end of an hour, a day, a week, than it could at the beginning?

Q: I'd like to add something to what the previous questioner said, about whether there can be a fulcrum on which to rest thought. There are two things here. The first is whether this fulcrum can be thought of in relation to the group's ethical, rather than its aesthetic, reference. The second point is completely separate: it concerns Leonardo da Vinci's idea of weight, which I can't remember

in detail but will quote in part. It goes something like this: "The lover moves towards the loved object like sense towards the sensible . . ." I don't recall the whole quotation, but at one point he says: "if the loved object is base, the lover becomes base, and if the loved object is good, it gives satisfaction and gratification." Then there is a reference to weight: "So the lover rests and the object settles there" – which I would like to put together with the idea of resting on something. I apologize, because it's a while since I read this quotation. I wondered if this resting, the possibility of putting one's weight on something, might be a reaction, in a group situation, to what we can imagine as the ethical reference – that is, the possibility of respecting other people's thought. The example that occurred to me this morning was Freud's essay on Leonardo da Vinci, where he puts forward a number of hypotheses about Leonardo, respecting his thought on the aesthetic level without doing violence to it. I'd like to know Dr Bion's opinion.

Bion: Leonardo was one of these people who appears to have had a very great mind, a very great personality; indeed, the remains he left still have a powerful effect on people who are living long after his death. Horace was another inhabitant who is supposed to have lived geographically in this area. His "Ode to Pyrrha" has worried a great many people: in it he describes the painful consequences of having fallen in love with Pyrrha's golden hair. In navigating that particular sea, he appears to have come to shipwreck and has hung his dripping clothes as a memorial to the experience. I find it very moving to see portrayed on the walls of an Etruscan tomb the costume presumably worn by the inhabitant. That is a pictorial representation of what looks remarkably like a similar state of mind: it seems to be expressing a similar difficulty with regard to the passion of love. Clearly there seems to be something which brings two different human beings together; whatever the outcome of their coming together, whether it is shipwreck or continued journey, it appears to be a very stimulating experience. So those who are disposed to launch themselves on the stormy seas of love are risking a painful and frightening experience of shipwreck. Our problem here involves not only being able to think intellectually, but also being able to feel emotionally. Let me put the question again: what wild thoughts and what wild feelings are you prepared to risk giving a home to?

Q: I've been nurturing a wild thought for about three-quarters of an hour now. I need to tell the story of a film I thought of when Dr Bion talked about omniscience, omnipotence and leaving space. Its title is *Phase IV*, and it's a science-fiction film. The plot is about two scientists, an ethologist and a doctor, who are assigned to investigate an invasion of ants somewhere in America. On arrival, they find totems, monuments built by the ants. Nearby, they build a "biodome". The ethologist bombs the monuments to smithereens, causing the ants to run amok. The men try to destroy the ants with a yellow acid. The surviving ants take away this yellow material a little at a time. Then these yellow ants surround the dome and build pyramids, or pyramid-like parallelepipeds – set up so as to reflect the sun's light on to the dome. At this point a very important new element is introduced into the story: a girl survivor of the yellow acid joins the scientists in the dome. The ethologist who was studying the ants *in vitro* is bitten by them, and the girl has a fit of hysterics and breaks the test-tubes. The ethologist is intent on destroying the ants, so he goes outside to smash the pyramids that focus the sun's heat on the dome and raise its temperature. But the cybernetician manages to establish a human relationship with the girl and, to make contact, makes a square for the ants – in other words, he tries to use this square as a language. The ants respond with a circle, with another smaller circle inside it. At this point the girl feels the need, or possibly the wish, to sacrifice herself – in other words, she thinks the ants want *her*. So she goes outside. As for the ethologist, he has been driven completely mad by the ant bites and, leaving the dome, is killed by the ants. The cybernetician is very disturbed by all this and goes to look for the queen: he goes down a tapering tunnel in the hope of finding her there. Instead of the queen, a hand appears, and then the girl. Then the film cuts to a different scene.

It ends with a man and a woman walking in the hills, which have been transformed by the ants – I don't know what happens then; perhaps they'll make another film.

Bion: What strikes me about this is that I cannot imagine how the adrenals could ever get a mode of expression, although I can see that through a relatively short space of time, a few hundred years, vestiges of their activity could emerge in the human mind. And then at last the

poor inarticulate glandular substances could find expression, aided by the machinery of film, film projectors and mass advertisement. So we get a modern representation of flight and fight which, with the combined wisdom of the human race, can produce a modern method of dispersal of the message which the adrenals presumably could never have expressed. In this way it might also be possible to add a little quota to the whole by drawing attention to speculative imagination and speculative reason, elaborating a continuation of the conflict between the capacities for flight, fight and dependence. So far, the human animal has been pretty good at destroying its rivals. But every now and then, it is not so successful: in 1918 there was an outbreak of influenza, or Spanish 'flu, or "pyrexia of unknown origin" – PUO. In a short space of a few weeks those minute objects – viruses – killed off even more human beings than human beings had managed to destroy in the war. Our capacity for self-destruction hardly requires augmentation; there are plenty of forces waiting to do the job and to put an end to such creative capacities as we have. Perhaps somebody would like to write the script for a film of a war between the adrenals and the gonads. Perhaps we should end by all being impotent or infertile, or perhaps make the world uninhabitable because there were too many of us. I shall wait – though I may not last long enough – to hear the continuation of that film. Perhaps it won't be just a film; perhaps at this present time we ought to prepare our minds and capacities for future dangers to which our present and past ones are just the *hors d'oeuvre*. The capacity for thought needs to be fostered so that it becomes much more capable and much more robust than it is. Even our ability here to debate is easily affected by the sight of a helicopter over the building, a dog barking, or motor traffic. An ability to think and debate which is as vulnerable as that is just not good enough. As a by-product of the discussion, we hope for a stronger, more robust and more accurate method of thought.

At this point the time that we heard about earlier in the meeting dictates to us again that we have to disperse.

Seminar 8

16 July 1977 – Evening

Freud was impressed by certain caesuras, but they are, in fact, multitudinous. Birth and death both seem to create a mental turbulence; it is possible that we ourselves notice the upheaval when we are born and change from a watery fluid to a gaseous fluid, from the amniotic fluid to air. But it is the birth of someone else which creates the disturbance in the already existing people – usually the mother and father. Death also creates a disturbance in the survivors. But that doesn't mean that birth or death are of any importance as far as the individual is concerned. We can easily imagine that if we fail to be born adequately that would create a disturbance; similarly if we fail to be adequately killed, or fail to die.

When I was studying medicine I became familiar with the saying, "Do not strive officiously to keep alive", meaning "Don't go out of your way to keep somebody alive, officiously". Thanks to the scientists it is now possible to keep certain bodily functions operating – for whose benefit I don't know. Recently there was a notorious case in which the parents were extremely anxious that all this apparatus should be allowed to cease functioning so that the patient, their daughter, could die. Their wish was disregarded. The antivivisectionists used to object to animal nerve-muscle preparations which were used in the teaching of students in physiology. The case to which I refer was one in which the human being was used like a nerve-muscle preparation. Cui bono? To whose benefit is it?

To get back to these periods which seem to create a powerful impression on living people: babies are born, and people die. Once we are alive, we can die at any time. So how many funerals are we going to celebrate? How many deaths are we going to exalt into ritualistic upheavals? Each one of us who exists at the beginning of a meeting,

like this, has ceased to exist almost every second of time that passes from then onwards; we have all changed into different people. What we were before that is not important; it rapidly becomes the past about which we can do nothing.

As I say, periods or episodes like birth, adolescence, latency, marriage, death seem to release an emotional turmoil, so a great deal of importance is attributed to these caesuras whenever they appear to obtrude into our notice. The emotional turbulence which is initiated is of some consequence because all sorts of elements, to which we don't usually pay much attention and of which we are not aware, get churned up and thrown onto the surface. They are often so noticeable that we give them a name – I tried to summarize it in a talk called "Break Up, Break Down, Break Through". I could almost say, "Choose Your Own Preposition". But we as analysts should use these words carefully; if we are going to talk about "break down" or "break up", at least let us be clear in our own minds by which coordinate system we are measuring the direction of the break. You need to make your own vocabulary and to be quite clear what *you* mean when you use a particular word, so that you always use it consistently. Pressure is put on us when people who are not used to speaking with care say, "So-and-So is having a breakdown." I don't think you should be seduced into the belief that the person concerned is having a breakdown – a break, yes, but leave yourself a chance to come to your own conclusion about the direction in which that break is occurring. Socially we don't need to argue the point; we can agree and fall in with the ordinary everyday use of language. But we shouldn't allow that to blunt the language that each one of us uses. It is possible, of course, in a group like this, that we might elaborate a common language which could be understood by all of us, but the essential thing is your own private language which has to be kept in good working order.

Q: An essay on truth and falsehood begins with a metaphor taken from Hans Christian Andersen's tale "The Nightingale". It goes more or less like this. A forest extended from the boundary of the Emperor of China's gardens to the sea. Sailors told of a nightingale singing in a tree in the forest. The emperor wanted to have this nightingale for himself at all costs and threatened his inept courtiers with death and destruction if they failed to bring it to him. In the end, a lowly kitchen-maid was able to help the searchers; the

Emperor had the nightingale, which made him happy, and the nightingale felt rewarded by the Emperor's delight. Seven sons of seven samurai were given his name. But the Emperor of Japan, who was envious, one day sent a gift of a mechanical nightingale to the Emperor of China. Its song seemed more beautiful than the real nightingale's. A music-master wrote seven theoretical volumes about the song of the mechanical nightingale. The real nightingale flew away in a huff. The mechanical nightingale unfortunately broke down, and the Emperor lay dying, from the pain of the loss of his music. The courtiers had given him up for dead, but that night the real nightingale came back to the Emperor, remembering how moved he had been in the past. Entering the Emperor's bedroom, the courtiers were astonished not to find him dead. He was standing up and happily bade them good morning. I won't report what the story says but, instead, my conclusion. After these seminars, I felt I understood that the truth might be displaced from the nightingale and found in the Emperor's suffering. Or perhaps in the suffering of the two Emperors. But I'd like to ask Dr Bion if a different vertex can be detected in this story – something about the truth that can rescue the situation. I'd been thinking about life.

Bion: One of the peculiarities of certain forms of communication is that they are hieroglyphic, pictorial – Chinese, for example. The objection to that method of communication is usually that it is somewhat clumsy and ambiguous. Indeed, according to Fenollosa, the number of characters which are used in Chinese hieroglyphic writing can be reduced enormously; it is said that only about four thousand are really necessary; the remainder, which certainly amount to at least ten thousand, are redundant. Take this particular fable: it must have taken quite a long time to transform it into present-day articulate European languages; the hieroglyph has to be changed into a verbal version of a pictorial image. For our purposes, in our vocabulary, I think it is necessary to cut down the characters to a minimum; the same thing with regard to the pictorial images which we have to use. What store of verbal images and articulate words belonging to an articulate language are we to keep to draw on? And how is that vocabulary to be integrated in order to express something which we want someone not ourselves to understand? In this group it would be a great advantage if we had a common language. You can see what a

nuisance it is when somebody like myself comes into the group and cannot talk a language which you all understand: it is a nuisance to you, and it is a nuisance to me.

Q: I'd like to say something – that is, I'd like to try to express this idea: what I have understood is that we need to try to listen. And also to see with our senses and . . . I'll stop there. Even though I feel that this causes tiredness and danger.

Q: . . . I felt from the beginning that deciding whether or not to express my thoughts did not matter very much, because I felt encouraged mainly to recover my capacity for internal listening – possibly by dropping my guard. But when I decided to express my thought, I felt anxious about the dependence and loneliness that could arise if someone were to listen to me and then go away. But the anxiety of loneliness and dependence could become intolerable if my internal listener also went away.

Bion: I am not sure what you feel is the problem there. Is there any reason for supposing it would go away?

Q: The internal listener might go away together with the external listener.

Bion: But if you know that, what is the difficulty?

Q: It might make it harder to express anxiety, to express my own thoughts, and increase the tendency to listen to them only inside myself.

Bion: The feeling of being dependent *and* alone is fundamental; it seems to antedate any ability to employ articulate or any other form of speech between two people. The first person with whom we have to be able to communicate, the most important person in this context, is yourself.

I used to try to deal with that sort of situation by writing or recording notes. Nowadays I don't bother. I don't know what I am going to say in response to the emotional situation in which I find myself here. Experience teaches me that I am sure to be dissatisfied with what I say, but it also teaches me that I have to put up with the fact that I am me and that, whether I like it or not, I have to tolerate my own way of talking and thinking. Here, I am dependent on having what I say translated into a more comprehensible language. But this happens in

any case; when I wish to communicate what I think to someone who is not me, then I have to use a language which, as near as I can make out, will be understood by the person to whom I address myself. I have to put up with the fact that I may not remember what I said in the previous session, or last week, or last year. On the whole I am persuaded that what I say and think has a certain coherence. I don't know what the coherence is, but I have to be reconciled to that.

Q: What is the place – the *topos* – where the individual and himself meet? The individual and the other, the individual and the group? Might it be the place where thought and action, spirit and matter, come together?

Bion: I am not particularly illuminated by the various descriptions of the mind or personality – ego, id, superego, and so forth. A Jesuit I know of speaks of the "arbitrium", a name he gives to a function which acts as a final judge. I am not convinced by giving any particular name to the fact that I seem to discriminate and choose to say one thing and not to say the other. I think there is every reason to treat our verbal communications as an action which is similar to athletic action. I see no evidence for giving it a name. Nor would I agree with people who somewhat contemptuously dismiss the whole of psychoanalysis and philosophy as "so much talk".

Tacitus describes how the Germanic tribes used a method by which a bard expressed himself, and in accordance with the reaction of the group to that aesthetic communication, the leader decided what impulses were to be translated into physical activity like going to war. There are also legends about the songs the sirens sang. Perhaps each of us may be able to make some contribution to this problem of "what is it?" or "who is it?" who decides in the republic of our own personalities which thought or action is to be translated into further action.

Walter Landor puts it in this way;

> There are no fields of amaranth on this side of the grave.
> There are no voices . . . that are not soon mute, however tuneful.
> There is no name with whatever emphasis of passionate love repeated
> Of which the echo is not faint at last.
>
> [Walter Savage Landor, *Imaginary Conversations*]

Each of us, so long as we live, appears to be able to record various experiences in the course of his lifetime. Something seems to be able to determine what, out of all that store, is worthy of recall. But there is still the problem of deciding what to do with it. We may be able to come to some kind of temporary conclusion as to how we are to decide. It is complex: a number of thoughts, ideas, feelings are stirred up, and almost instantaneously we put them into an order of precedence. That is very much of an intellectualization, and I am not particularly satisfied that it is a fair representation of the facts.

Q: In all these seminars we have touched upon the subject of death, and I believe that, if what we have said is to be coherent and efficacious, we need to be able to encounter the Buddha – and also to be able to kill him. I'd like to ask Dr Bion if he thinks that the discussion we are having at this moment has any connection with Freud's reflections in the short paper where he is accompanied by a poet ["On Transience", 1916a]: together they see a field of flowers and reflect that although they will die, it is nevertheless worthwhile to live and work.

Q: I, too, would like to ask something. When you spoke about the listener and establishing a language of one's own, does this have to do with bringing about a situation where, when we say something in the course of analysis, we say it first of all to ourselves, and can this give rise to growth?

Bion: I am not sufficiently acquainted with the *Upanishads* to be familiar with the earlier formulations about the human mind and the human spirit. There are certainly some works which appear to establish a contact with Western modes of thinking. The *Bhagavad Gita* is one of them; there is a distorted version, by Fitzgerald, of *Omar Khayyam*; there is a French version of *The Iliad* which is said to be the best there is. There is a curious similarity between various races and times – for example, the prophet who is supposed to be able to voice the opinions of God. Moses, Jesus, Mohammed are all said to have expressed the will and views of God. The Muslims seem to regard the Hebrews as having gone astray, and to have done so markedly on the occasion when Moses descended from Sinai and found them worshipping the golden calf. The Christians likewise, according to Mohammed, have made the mistake of deserting to a polytheistic religion by not being faithful to a monotheistic one.

Although the subsidiary gods are, as it were, clothed in the characteristics of sainthood, it is a return to polytheism and a departure from monotheism – the vital and essential part of the religious outlook. Accordingly, the Muslims regard both the Hebraic and the Christian religions as having departed from the true religion. What about the psychoanalytic sainthood? Do you detect any signs, in the mental sphere, of stratification? Kleinianism? Freudianism? And in what direction would you say these strata are discernible? Is it possible to detect in our debate here any signs of what I call "stratification"? Geologically, of course, we can see these strata – sometimes they are up-ended like pillars; sometimes they lie horizontally. We can imagine that in a time of upheaval the strata become bent in all directions; the various religions and patron saints are fragmented and can only be described as being in a state of turbulence, of constant movement. And then it gives way to a period of relative quiescence and apparent security. But the strata still remain and can still be detected – these multitudinous gods, together with their followers.

Pressure is frequently put on an individual to suppose that he or she is one of these important people. It is very misleading – there are fashions in these religious attitudes. The god who is thrown up and exalted, rapidly disappears. Remember the poem,

> "My name is Ozymandias, king of kings;
> Look on my works, ye Mighty, and despair!"
> Nothing beside remains. Round the decay
> Of that colossal wreck, boundless and bare
> The lone and level sands stretch far away.
>
> [Shelley, *Ozymandias*]

I don't think we should be too depressed if we can see these stratifications appearing, or, to change the metaphor from geology to religion, these varieties of polytheism. We can regard them as temporary, transient phases in our journey.

Q: May I ask Dr Bion what he thinks of the daily organization of one's own mind, and whether it can facilitate dialogue with one's internal interlocutor.

Bion: I think it is dangerous to assume that we are in any way exempted from the general movement in a community. Freud described a situation in which the mere change of the observer is

liable to be mistaken for a new discovery in psychoanalysis, or a new form of psychoanalysis. I mentioned before the point about modern geometry being implicit in Euclidean geometry; at some time it became explicit – it seems to be almost accidental, as if, for example, the Cartesian co-ordinates were a by-product off the main line of Descartes' thought, and yet very important.

Q: I wanted to say that this evening I'm constantly thinking of a poem. It describes the act of finding names for things. The poet seems very pleased, very happy, that he has this capability. At the end of the poem, he imagines he can see a beautiful ring at the bottom of a lake of particularly clear water. He also realizes that he is absolutely unable to think of a name for this object. But this seems only to increase his joy. So I'd like to ask Dr Bion if he thinks that this difficulty in naming – like the particular difficulty we sometimes have in making the implicit explicit – might perhaps be added to the series of caesuras we have been talking about . . .

Bion: It could be a caesura which impressed him, and he may be able to communicate that experience verbally to you and to others because of his capacity as a poet.

I think we are all liable, in accordance with our individual natures, to be impressed by some particular caesura which may not mean very much to other people. One of these impressive things is what we might call "cure". There is a tendency for the group to pursue the shadow of a caesura; we pursue a particular relic or idea as if it really existed. In psychoanalysis there is an implicit idea that if we go through that discipline we shall achieve a cure. I see a certain difficulty: there is one particular capacity which I have come across over and over again – so much so that I would regard anyone as being extremely deficient if he couldn't make a fool of his analyst. A patient who couldn't make a fool of me must indeed have something wrong with him. It is difficult to tolerate: consider what you would feel about a person who succeeds in making a fool of you. Nevertheless, anybody who aspires to helping his suffering fellow men and women has to be sufficiently robust to survive being made a fool of.

When I happened to get swept into hospital in England, I saw the elaborate laboratory tests and auxiliary forces of nurses and hospital wards used to cure diabetics. These people were having extended to them the resources of the Welfare State. Part of it consisted in being

allowed to be visited by their friends and relations. So, on the one hand, there was extended to them the diet in accordance with the findings of medical science about dietetics: on the other hand, their friends and relatives, taking pity on these poor people whose freedom was being restricted by the cruel hospital doctors and nurses, would see to it that they were plentifully supplied with the kind of food that they really liked. I didn't stay there long enough to see what was the outcome of that particular story, but when we are proposing the correct – in our view – mental nourishment, we also have to be aware of the fact that there are plenty of other people who will supply what *they* consider to be the correct mental nourishment. You will probably soon come across a professional paper depicting the need to reassure and comfort terminally ill patients by telling them something to act as an antidote to their belief that they are dying. I wonder what chance advocating the truth would have against forces of that nature.

Seminar 9

17 July 1977

We are all concerned with mental health from a responsible position. I am not considering as a part of our immediate discussion what we as individuals feel; as people in a position of responsibility with regard to patients, what we feel mentally or physically is a matter of no consequence whatsoever. It matters to us individually, but to no one else. It doesn't matter how tired we are, how physically or mentally ill – all those are matters of complete indifference. They are only *facts*, like any other facts about which we can do nothing and about which nobody else is going to do anything either. Your mental or physical health is a fact like the weather or the geographical location in which you are working, which is otherwise of no consequence. Whatever those facts may be, as responsible people we have to exercise our skill; we have to be capable of thinking clearly, no matter what is going on.

Our problem is how to be sensitive to the sufferings of people who come to us for assistance, but not to be so affected by them as to interfere with our thinking clearly about the work in hand. In certain situations we can be unmistakably aware of the danger in which we are, particularly those in which we are threatened with physical violence. It is still important that we should continue to think clearly even when it is also clear that our lives are in danger. But most of the time, that sort of danger is not at all obvious; our circumstances can appear to be comfortable and consequently reassuring.

In war, most of the people who are engaged in the combatant forces are aware that the fact that there are medical services is really irrelevant. It could be very seductive; it might seem to exert such a pressure that troops would like to be looked after instead of having to fight the enemy. Even in putting forward that picture I am drawing attention to something which is relatively simple. It is difficult to

realize that analysts and those concerned with helping mental sufferers face any dangers. In the mental sphere one point can become clear: we find ourselves alone in a room with a particularly violent patient; there is not much we can do about it because most of us haven't the muscular, physical strength to cope with such a patient. It *is* possible to be prepared to use such physical capacity as we have. For example, if your room is high up, then it is obvious that the patient could resort to throwing himself – or the analyst, of course – out of the window. Therefore, during the time that you are seeing that patient, place yourself between him and the window. It would, in fact, be preferable not to have the consulting-room in such a position that it would be easy for the patient to commit suicide or murder by using the distance between the room and the earth below.

I found this a somewhat alarming and yet stimulating fact when I was director of the London Clinic of Psycho-Analysis, where there were no lifts and *all* our patients had to climb to the top of the house to be seen for analytic purposes. I cannot remember now how many stairs they had to climb to get to the consulting-rooms – and therefore how many stairs there were available for throwing themselves down with disastrous consequences. So we took various palliative steps which were supposed to act as an antidote to the situation in which we found ourselves. I don't know who felt better as a result of those steps, but I am reminded of the statement made by a famous British commander-in-chief, Wellington, when reviewing his troops: "I don't know what effect my troops will have on the enemy, but they certainly terrify me."

The best and the most highly qualified collaborator we have in analysis is the patient; the outcome of the meeting depends on a collaboration between the analyst and the patient. It can be very frightening if we also allow ourselves to be aware that we are all alone with, and dependent on, the patient. The patient may have outstanding athletic ability, and a manic state can lend great force to that ability. So a patient who is trying to prevent you from being helpful, creative or constructive sets you a considerable problem. How are you to continue to think clearly while someone is trying to murder you?

That is a comparatively simple situation, because you have the evidence of your senses and of the source from which the danger is arising. The position is more difficult when you are dealing with what we believe to be a mind, a spirit, a soul – or whatever the fashionable

term is for it. I am sure that we all have experience of a great deal of education. So we are probably familiar with words like "spirit", "soul", "ego", "Buddha", "Brahma" and so on. Paradoxically what we may not be quite so familiar with is the name which would seem to us to be most suitable for the "thing" that we are dealing with when we are all alone with someone who comes to us for help. If the patient tries to throw you out of your window, it may be difficult to appreciate that he comes to you because he wants help. This same force which may be manifesting itself in a physical struggle with you, is what he has to live with. So he may be afraid that you will not be able to resist him physically and is terrified that he himself may not be able to resist or deal with that terrifying force.

In the practice of psychoanalysis – as opposed to the theory – your problem is, are you able to see such facts as are available? Some of them are easier than others: a physician can train his powers of observation so that he can see that the patient's countenance is not displaying a beautiful colouration of the cheeks such as would be appropriate to exercise or perfect health; he may be able to distinguish between the blush of rude health and something which he can say, if he understands the language spoken by the body, is the sign of an infection. The patient may be hostile to the mental helper, whether he is an analyst or whatever his position. What is the source of that hostility? Does it arise from within the individual, or is it an infection derived from the culture of which he is a member?

I have lived long enough to have had the experience of knowing that at one time psychoanalysis was all the rage amongst the intelligentsia. I am sure all of us can remember times when particular attitudes or beliefs were fashionable. I remember when it was fashionable to read *The Forsythe Saga* [John Galsworthy]; it was then forgotten; it was then revived, thanks to the dominance of television and the evidence of the eyes. So that story was rejuvenated – apparently. However – and this is a difficult point to describe – what really matters is the *real* Forsythe Saga, the fundamental story, the facts, reality. The only thing that I can call it is "the truth". That is not going to be affected by the fashion or by whatever we may happen to think about it.

Changing over to something more scientific like mathematics: the visual geometry of Euclid – lines, points, circles – proved gradually, in the course of a hundred years or so, to be inadequate to the

human beings who used it. But I think that there was a *real* geometry which was also, as it were, trying to get expressed. Putting that in a different way: real geometry was implicit in Euclidean geometry. That truth, that *implicit* truth, was a kind of sleeping beauty waiting to be rescued, waiting for someone or something to break through the barriers of thorns and weeds and awaken the true geometry. In other words, Euclidean geometry and all its adherents had built up a barrier against the emergence of the truth, until at last the dominance of the eyes and the pictures of lines and circles was overthrown by the coordinate discovery and the application of algebraic thought to geometry. The truth hadn't altered; the truth that was implicit in Euclidean geometry became explicit.

This is one more example of the point that I have already made: an activity like psychoanalysis is fashionable, and fashions change. If, therefore, there is any truth in psychoanalysis or any truth in psychiatry, then it would be helpful if any of us could do anything to make that truth explicit. But it does mean cutting through an enormous growth of brambles, thorns, rationalizations. What we cannot afford to lose sight of is the main goal – the truth. Our own mental capacity has to be nourished, but there is nobody to choose for us; we have to be capable of respecting the truth whether that truth is expressed by our patients, our colleagues, our musicians, painters or religious authorities. So anyone who has respect for the truth deserves our support, and we have to deserve it. If we are to help our manic, depressive, schizophrenic or neurotic patient, we ourselves have to be worthy of respect. That can be partially dealt with by going to analysts and others who might help us to get to know who we really are. But in the position in which we find ourselves – a position which, it could be said, we have inherited – we *are* the authority, we *are* the parents, and there is no one for us to go to excepting ourselves. To modify that statement: while attempting to help a patient, as a sort of accidental fringe benefit we also learn something about ourselves.

To fall back again on the simple model of actual physical warfare: if, by any chance, we survive, we can learn something about ourselves. A book written in the First World War described a situation of perpetual and never-ceasing war – the war of the mind. The writer quoted the statement which was made long before psychoanalysis had even been thought of: "From that warfare there is no release". Here we can make breaks in this discussion, take rests, but that does

not mean that the warfare takes a rest – it does not. Disease – mental disease, physical disease – does not take a holiday. That is why we have to be so robust, so healthy. Whatever our difficulties may be, we have to remember to be concerned not with our problems, but with the work in hand – the work which never stops whether we are there to do it or not. There was a famous warrior named Crylon to whom Henry IV said, "Go hang yourself, brave Crillon; we fought at Arc and you were not there."

Q: I have always felt that what we think about other people is bound to have some effect on them, even if we don't reveal our feelings.

Bion: That awareness could be regarded as part of the evidence for the existence of the human mind. It is usually fairly easy to see that you can be affected by a physical contact with someone or something which is not you. A child may bump into a table or chair, or hurt itself by falling down; it then wants to hit the table or chair or the floor because it has been naughty and has hurt it. The point is not quite so easy to see – if one can call it easy at all – when you are dealing with states of mind; that is when you are aware that you have come "in contact" with somebody who is not you. That "character" does not appear to be observable by what we have hitherto regarded as our physical senses – our sense of sight, of smell, of hearing and so on. Nevertheless, even an infant seems to be able to tell when it is all alone and also when the object on which it depends is present. In that respect the discovery and awareness of dependence, and the discovery and awareness of being all alone, are fundamental. Those fundamental feelings, thoughts and ideas can still be stirred many years later. Of course, it is obvious that we are dependent on the existence of something which is not us and, at the same time, that we are alone with the thing on which we are dependent. But as analysts we depend upon and are alone with what we call "a mind". It is therefore important that we should not be overwhelmed by the latest fashion either of belief or disbelief, but should still remain capable of exercising such judgement as we have with regard to facts which are insensible.

At a time of turmoil, at a time when the leaders of the country were carrying out a revolution against the existing order, Milton wrote, "So much the rather thou, Celestial Light, / shine inward, and the mind through all her powers / Irradiate. . . ."

As analysts we have to make contact with somebody who comes to us for help. We are just as fallible, just as vulnerable, as any officer, NCO, or any one of their troops. As responsible people we do not have the privilege of being able to be ill, or to run away, or to be dominated by freely expressed emotions. We are just as much cowards as any of our troops; we are just as fallible as anybody that we are trying to help. In one way or another, we find ourselves inheriting a position of authority; how we have got there it might be very difficult to say. Even if you look back on the history of your own life, it will still be difficult to say how it comes about that you are in the position of being one of the authorities, one of the helpers. Victor Hugo described the experience which is shared by an army and its opponents as one of terror. We harbour the illusion that the enemy is very powerful, brave, well-trained, well-equipped: the enemy probably shares the same emotions about our own army. But if a poet is able to ignore these uniforms – mental and physical – then it is possible for him to see that the experience which is shared by both armies is one of terror.

This complicated situation was illustrated at Christmas time in 1914 when the opposing troops of the British and German armies fraternized and played football against each other in no-man's land on the day which was supposed to be the anniversary of the birth of Christ. To imitate Wellington: I don't know what effect that had on the enemy, but I can say that it terrified the Staff.

The further we get from the fighting line – the practice of psychoanalysis, mental health, psychiatry – the more we become aware of the ferocity of the staff, the ferocity of the theoreticians. If they had their way, the bloodshed would be terrible.

This seems to be what the speaker who asked this question was talking about. I am sorry to have given such a long-winded answer – the thing itself is much shorter: the real experience of affecting the patient and of being affected by the patient is almost instantaneous.

Q: I'd like to take up Dr Bion's earlier invitation to talk about difficulties we have met with in our work. Let me tell you about a patient who was diagnosed with a fatal disease – acute leukaemia – after two years of analysis. The patient was only partially informed. He dreamt that *he was on a couch or table, which was both the analyst's couch and the transfusion table; he was about to fall, but then seemed to be resting on a pivot, about which he was able to turn horizontally*. In this

situation you can't say that the dream symbolizes time – the clock concept – but you have to say that the patient himself *is* time: he is clock time. If the patient is time and not the symbol of time, let me ask Dr Bion what the analyst must be, or can be.

Bion: We can approach this problem, first of all, from a general standpoint and express a general principle. We conform to a certain discipline which we have acquired or been taught. However, as a practising doctor or analyst, you close down your view and concentrate your attention on an area which is more restricted. To put it in more philosophical terms, the general principle is being transformed into a particular instance.

If you were to ask me what my job is, I couldn't tell you, but I can tell you what *I* think it is. It is up to you to decide – you are the only person who can – what *you* think your job is. Narrowing this down further, let us look at this particular person of whom I have hearsay evidence which I have been told by the last speaker. This patient's death doesn't interest me any more than his birth. That tiny little bit between birth and death – that *does* interest me. It may be a very small space indeed, because there is such a thing as infant mortality, death at birth – or death at death. So I don't think there is a great deal in this tiny little space between the moment of being born and the termination of that life – as I say, it can terminate virtually at the start, or even before the person ever becomes "conscious", as we call it.

This particular patient is said to be dying. That again doesn't impress me; we are all dying since we are, in fact, living. But it does interest me if the life and the space which is left is worth living or not. We do not know what we shall die of – I am sure that somebody sooner or later will oblige by diagnosing it. In this instance, it is said to be lymphatic leukaemia. It might be something else; it might be the death of the person's mind. I have come across people whose bodies still survive, but as far as their minds, spirits or souls are concerned they are dead. To turn again to this more particular view, this very small view in which we don't bother very much about all these general principles, then we need to focus on the question, is there any spark which could be fanned into a flame so that the person could live whatever life, whatever capital, he still has in the bank? How much *vital* capital has this person? And could he be assisted to use that capital to good effect?

Although this patient is said to have leukaemia, a fatal complaint, since I cannot foretell the future I don't know what he will die of; I *do* know that it won't be death, because death is not a disease. That is simply one of these impressive caesuras.

This patient is living in a certain culture – I gather that he hasn't been told that he has lymphatic leukaemia, and I doubt that it would mean much to him anyway, if he is a layman. but I have no reason to doubt that he can interpret certain physical facts. What is his interpretation of the sort of behaviour to which he is subjected by his culture? Who does he think the analyst is? Is he somebody to help him to live, or to die? Most of us – to widen the view again – can be relied upon to indulge in plenty of activities which are much more likely to kill us than to make us live; we take things into our alimentary systems which are poisonous. There is nothing wrong with alcohol, but we can use it for purposes of poisoning our physical system; there is nothing wrong with taking air into our lungs, but we can indeed breathe polluted air or smoke and inhale the fumes. In Britain there is a warning compulsorily printed on all packets of cigarettes and on all advertisements for tobacco: "Smoking is injurious to health." That statement, that warning, has become part of the ritual of smoking; it is part of the beautiful, seductive picture of the pleasures and delights of smoking. It is made respectable and even scientific by saying "Low Tar". I have never smoked tar in my life – I am not interested in buying tar, so I can see how virtuous I am because I don't smoke tar. Now, I can get on with smoking tobacco – unless, of course, the manufacturers should feel it was more profitable to sell me low tar. I can see that it might be cheaper to make a big cigarette with a large wad of cotton instead of the rather more expensive tobacco leaf.

Narrow down the view again to get nearer to what we are concerned with: a mind. While the body of this patient is dependent on various sorts of somatic nourishment, what are we to provide him with by way of mental nourishment? By this time the analyst certainly knows a lot about the patient, so he could tell the patient all sorts of things about lymphatic leukaemia. To widen the picture, I could say, "In my opinion he should tell him the truth." Narrow it again: what is the truth? What does the analyst know about it, and what could the patient understand if the analyst tried to communicate with him?

I am sorry to take such a long time to discuss such very simple points. We still haven't got to the point – namely, what the analyst is to say that this patient could understand. It is possible that the patient could feel that this particular helper is more interested in his living a life worth living than in the various rituals and procedures which are appropriate to dying. If that is the case, he could feel that this object with which he gets into contact – even if it isn't a physical contact – might be friendly and helpful. That may or may not be psychoanalysis – I am not bothering with that because I am not interested at this point in theory but in practice, in life. Whether the patient is at the beginning of his life, at birth, or whether he is at the other end of the spectrum, at death, he can feel the presence of a friendly or health-giving object.

I think it is very difficult to resolve to avoid the truth and to start telling some sort of agreeable lie. It is hard work, it doesn't seem to me to be worth doing, and, as a result, one's own mind, character, personality is polluted. Our capacity to speak the truth dies through the lies we tell other people.

Let us try to bring to bear on this problem the combined wisdom of all of us. If you were in this position, what would you say to the patient? Apparently he had what he calls "a dream". That means that he was in a different state of mind from that in which he is when he is wide awake, "conscious", and carrying on a conversation with you. The dream he tells you is, in fact, what he, in the state of mind in which he is when conscious, thinks happened when he was asleep. In this conversation, what should we be most impressed by? The fact that he is awake and conscious? Or that he is also in the state of mind which is a "hangover" from the state of mind in which he is asleep?

In the quotation I mentioned from Milton's *Paradise Lost*, he says, ". . . there plant eyes, all mist from thence / Purge and disperse . . .". Can the analyst forget all that he has heard or learnt about lymphatic leukaemia? These "facts" form a mist, obscuring the truth which might help this person to live his remaining hours, weeks, months, years perhaps, in a way that is worth living.

It might be possible to draw the patient's attention to the fact that he fears that when he is off his guard – as he is when he is asleep – then the analyst may subject him to the same sort of treatment as all the other doctors. So that what is in fact only a psychoanalytic conversation would appear to be something which was sucking the

vital substance out of him. His blood may be very defective stuff – it has a lot of white cells which are not beneficially operative – but it is the only blood he has.

Translating that into mental terms: the patient is well aware of the defects of his character. But he does not want to lose such soul as he has. You could try saying, "You are afraid that I am trying to cure you, but that my cure is going to kill you by taking away anything good that you have." I don't want to attach any importance to that particular interpretation, because, in fact, it is worthless – *I* am not treating this patient and therefore I don't know.

There is no outrage that I know of which is greater than the one you permit when you allow someone not yourself into the privacy of your own mind. So the patient can be frightened of the analyst, and frightened of himself for talking to an analyst. The analyst will certainly be subjected to pressures; he is liable to be attacked – "Why tease a dying man with all this stuff which might be appropriate *if* the patient was going to live?" It is difficult to defend your position, which would mean saying something like, "Yes, but this patient has still got a few minutes, hours, days, weeks left to live, and that is why it would be helpful for him to know what I am telling him." Whether we are in good health or whether we are suffering from a fatal disease, it may still be worth while to know how to use our minds.

Q: And the survivors? What do you have to say about the survivors?

Bion: The survivors, of course, are able to go on thinking and feeling. The fact of death is so impressive that it nearly always stirs up a turmoil; thoughts and feelings which we have forgotten become conscious. In that way we have an experience which is more powerful than any psychoanalytic experience because it is real life. In an organized, socialized group, the death of an important person – or the death of a symbol of an important person, somebody who might represent or remind you of a father or mother of a nation – is dealt with by elaborate rituals. Sometimes they involve the participation of the armed forces, who make a slow march behind the body to the place of burial to the accompaniment of pieces of music like the "Dead March" from *Saul* [Handel oratorio], or, "The Flowers of the Forest Are All Gone Away" [traditional: commemorates those killed in the Battle of Flodden in Scotland in 1513]. As soon as the body has been disposed of, the troops, representing the nation, march off in quick

time. The slow march is the depression, mourning up to the moment of burial, and then – quick march! That, I think, is a profound group reaction: it is a reminder that when the dead are dead, that is the end of the story; it is time to get on with living.

I think we might also consider the reciprocal of this – should we interfere with anybody who *wants* to die? Does the fact that we purport to be helpers entitle us to interfere at all with somebody who does not want to be helped? There is a difficulty here: we have to consider what evidence leads us to suppose that the individual does not wish to be interfered with or to pay any attention whatever to such warnings, opinions or advice as may be conducive to longevity. It matters very much, of course, whether the person who does not want to live would pollute the atmosphere for the survivors.

Who or what are the forces which are liable to be conducive to *mental* death? It would be useful to know what is good mental nourishment – which would imply also knowing what is bad. The advantage of a group situation is that you can survey the entire group and possibly detect sources of infection in it. The entire group could remind you of various aspects of your own personality at different stages in your development. Instead of seeing it in narrative form, from A to Z, you could, so to speak, see all the letters of the alphabet spread out on one plane. That is a pictorial way of getting rid of the time component – we exchange a temporal component for a visual emphasis of the spatial component. Here and there you can see for yourself the sort of behaviour, activity, which has been designed to destroy the group's capacity for learning or developing its own abilities. When you feel the need for silence, and possibly the chance of hearing your own thoughts or ideas, the silence can be destroyed. The noise becomes so great that you cannot hear yourself think. This is one of your problems if you are concerned with education: with trying to make available, to people who don't know, such experience or knowledge as you have. Parents find themselves in the same position *vis-à-vis* their children – they would like to do something for them. And it also applies to the human family, not simply blood relations.

Q: I have on occasion given some attention to what you might call a state of slight chronic depersonalization – that is, a state in which mental capacity is diminished both in waking life and in sleep, so that the possibility of experiencing facts or emotions, or even sense

data, is reduced. It seems to me that such a situation has components that stem from the group and from the individual. Can Dr Bion tell us how we might define or find coordinates to locate the source of such a mental state, and why – at least in my own experience – emerging from such a situation, even if it is acknowledged to be useful and growth-promoting, proves to be painful, dangerous and tiring.

Bion: As usual, it is easier to talk about it in its more exaggerated forms: a patient who never seems to mention himself at all – I am thinking of a particular patient – but constantly pours out information about the characteristics of a very great number of people, all members of the society of which he finds himself a member. Such a state as that could be a later stage in what Melanie Klein described as an omnipotent phantasy of infancy, the phantasy of getting rid of the character or personality. The grown person sees faults everywhere: that seems to me to be not dissimilar from this theory of evacuating all the characteristics which are feared and disliked, and then being persecuted by them from outside. Every analytic interpretation, every person and thing, comes over as a persecution because they remind the patient of himself and his fear of these selves which become reunited in his own personality.

Let us get back to this *chronic* case. Could we again fall back on the group situation and say that between the lot of us we represent a *chronic* state? We are not only individuals to whom we attach some importance because of our individual view of ourselves *as* individuals, but we are individual bits out of a total pattern. What I want to know more about is what is meant by this word "chronic". Is it, in fact, a reference to "chronos", to time? What is this "chronic" or "chronos" about? What is the meaning of it?

Q: I think I can be more precise: it seems to me that "chronic" describes a state where there is no clearly definable distinction between two situations. Second, it seems to me that "chronic" also has the property of not being easily distinguishable, in the sense of not manifesting itself as an obvious fact.

Bion: This may be the sort of thing that psychoanalysts are trying to describe when they talk about a "latency period". I find it easier to believe that what we have just had described to us is a latency *state*

rather than a latency *period*. In this way, the patient can at any time present a somewhat featureless landscape. Is there anything which sticks up above the level of uniformity? One thing, of course, occurs to me at once – namely, the presenting quality of nullity. I will try to put it pictorially by reminding you of the termination of the fifth book of the *Aeneid* by Virgil: he describes Palinurus, who was the helmsman of the ship which is to give directions to the entire fleet. Somnus presents himself to Palinurus and puts forward the seductive view that all is going well. The sea is calm, there are no clouds, there is no danger anywhere. Palinurus, however, says that he is not so innocent as to be taken in by the calm face presented by the Mediterranean Sea. He ties himself to the tiller and to the stern sheets, but the god hurls him into the sea with such force that he is drowned and carries with him the stern of the ship. Now look at the calm and uniform surface presented by this patient – there are no features. What has happened to the storm?

What is to be said to this patient? There must be something which causes his musculature to react and to bring him into the analyst's view. We could point out to him that there seems to be absolutely no reason whatever for coming to talk to an analyst. The only thing wrong with this story is the patient's presence. So we could try to draw attention to the fact that there is a mystery which confronts the pair of you, and that is the mystery of a fact.

If you draw the patient's attention to this fact, then he may be able to contribute something further; he may not know much about himself, but what he does know is a great deal more than anybody else is ever likely to know. The patient knows – nobody else can – what it is like to be him and to have his thoughts and feelings. So if you can draw attention to this mystery that he is in the room, then he may be able, from his vast store of knowledge – it *is* vast, even if the patient is a child – to throw some further light. And then it may be possible for you to give another interpretation.

Take the previous patient we heard about: if he is able to interpret all these peculiar facts about a hospital ward, a bed, hypodermic needles and so on, what does he think they mean? What does *he* think is the interpretation of all that apparatus? Why talk to the analyst?

One could say that the question is the same in both these cases: why talk to the analyst? Of course, it could be because the patient

is sure that the analyst knows nothing about him and will not say anything frightening or disturbing. But that is very unlikely, because most of us have in our time been told stories of one kind and another with the express purpose of terrifying us. We even play games like soldiers at war. But what is the game they want to play with the analyst now? Why do these two people talk to the analyst? What is it a part of? What is this conversational intercourse about? I borrow a term from the sexual experience because I think that there is something in the capacity to converse which is not altogether unlike the capacity to have a physical relationship. The psychoanalytic conversation is a kind of childhood game, just as a childhood game is a kind of implicit reality; it is referable to something in the present. This group meeting is referable to something we don't know about – namely, the future. Are there some vestigial remains in both these conversations? Is there something which reminds you of the wreckage, the vestiges of a previous conversation? Are there any vestiges, any discernible bits, of wreckage which remind you of love or hate?

Here we can assume that there must be some reason for wanting to meet together. That doesn't mean to say that our feelings of dislike or hatred have disappeared, any more than the storms have disappeared for ever because the surface of the Mediterranean is calm. So even as we survey the dominance of the friendly relationship which causes us all to come together, what about the vestiges of the *rest* of our personalities? If we want to break up the meeting or destroy the furniture, what has happened to those impulses? Could it be faintly reminiscent of civilization itself? There is a thin film of civilization which covers all our human community. The United States, the United Kingdom, and now the United Nations – how united we all are . . .

Francesco Corrao: The group is probably a place – *locus* or *topos* – a privileged place where space and time, feminine and masculine, hate and love, truth and falsehood, all come together. Now, this coming-together is violent, hard to bear and hard to transform. So we need the support and guidance of a way of thinking and a method that is problematic and unifying at one and the same time. My feeling is that Dr Bion has supplied us – is supplying us – with this way of thinking and that he himself represents a strength in the here-and-now, because he embodies the strength of thought – its function, its use

and its communication. These group research centres – the first, the Pollaiolo, and then the others – concentrate on an area defined by the relationship between the group and the analytic function.

After all, it is worth remembering that the Bionian view is generated by an extremely intensified and amplified analytic experience. My feeling – or perhaps I should say, our feeling – is of deep gratitude to Dr Bion, for having enabled us to partake of the depth of his thought.

Bion: I thank you very much for that expression of gratitude. I hope it doesn't appear to be ungracious if I say that I can compare your description of my contributions with the fact of which I am aware and which I don't very much like. The nearest image I can give to it is this: like a leaf falling off a tree – one never knows which side up it will land. And when I look back on what I know about my life, I would never have been able to guess that I would be here today, at this time and in such a position.

There is a passage in a poem by Yeats, *Solomon and the Witch*, in which he talks about "Choice and Chance":

> And when at last that murder's over
> Maybe the bride-bed brings despair,
> For each an imagined image brings
> And finds a real image there;
>
> [W. B. Yeats, *Solomon and the Witch*]

"Journeys end in lovers meeting / Every wise man's son doth know" [Shakespeare, *Twelfth Night*]. I don't think they end in lovers meeting; they *start* at that point. Is there any vestige, do you think, in this hospital bed and the analyst's couch, any remains of the possibility of a loving or positive relationship between this person who calls himself an analyst and this other person who call himself something else? What is this group likely to give birth to? What thought or idea or action? And what relationship is likely to occur between it and some other group? Love or hate? Fight or flight? Dependence or freedom?

A PARIS SEMINAR

1978

'A Paris Seminar' was previously unpublished in English. The seminar was held in Paris on 10 July 1978 and was organized by Dr Salomon Resnik. It was published in French in 1986 as 'Une topique groupale. W. R. Bion et le groupe', in *Revue Psychotherapie Psychanalytique de Groupe*.

A Paris Seminar

INTRODUCTION

This seminar, held in Paris on 10 July 1978 and organized by Dr Salomon Resnik, was published in 1986 in the *Revue Psychotherapie Psychanalytique de Groupe*.

It has not previously been published in English. I am grateful to Dr Luis Goyena for his very kindly sending me two audiotapes in May 1997 from which I have made this edited transcript.

Francesca Bion
1997

10 July 1978

Bion: I must explain why I have to speak English. It is partly because I don't speak French, although I have learned or been taught French as it is spoken in the English Public Schools, but it is not the sort of French that you would understand. There are other reasons which will become clearer as we go on with our discussion.

I would like you to regard this as a working conference in which this problem is one which faces all of us. For example, a young man of twenty-five complains of having an unsatisfactory family life; I am not sure what family he is talking about, and in the course of a preliminary discussion I ask him his age and he says forty-two. Forty-two? But I said twenty-five just now. As I see him more closely I notice lines on his face, and every now and then I think he looks more like sixty-two than forty-two or twenty-five. Well, what is his age?

The first question I put to you is, will you take this patient or not? I am not suggesting that you should tell the patient or me or anybody else, but what do you tell yourself? If you want to write down your immediate impression now, it would perhaps be interesting to you to make a note saying "yes" or "no". To answer that question I propose to use a procedure in which I assume a "vertex" from which I could form some impression as to whether I want to see this patient again. Suppose you walked into a bookshop, picked up a book, turned a few pages and read what I have just said. Would you put the book down and pass on to another? Or would you like to turn over some more pages before making up your mind whether to read that book or not? So there's my second question: are you interested in this story; do you want to read any more of it?

I'll try another one: suppose it was a piece of music you were hearing. Would this sort of music interest you? Would you decide to

go to a concert and hear the rest of the piece of music? Or would you decide that it was not your kind of music? That is another vertex. Of course, in reality we haven't so much time, but here we can play this little game.

Changing the vertex again: suppose you were walking through a building and saw on the ground a pattern of colours thrown by the light coming through a window. Heredia, in the poem "Vitrail" [reproduced in the Appendix (p. 213)], describes the effigies on the tombs: they cannot see, cannot hear, but with their eyes of stone they see these colours spread out on the floor. As this patient is talking to me and the light falls on this conversation, what colours do you see? Do you like them? Would you like to spend some more time there? Would you like to study the window through which the sunlight penetrates to find out what sort of design there is in the glass of that window. I won't suggest any more because I would like you to think of various vertices which you can employ when confronted not with a book, not with a painting, not with a window, but with a person. What sort of shadow does he cast in your mind?

Getting back to the analytic situation, shall we tell this patient to come again? Shall we, as it were, open another page of the book, or listen to some more bars of music, or shall we stop there? Each one of us has to answer that question all alone. I am not asking you to take a psychiatric vertex at this point – it is too early. You have only had a few sentences [of conversation] and only a few moments in which to see this man. Do you feel inclined to say, "Well, I think I had better see you tomorrow", or next week, or "I would like to see you again in a month's time"? Nobody can tell you what to do because nobody knows what kind of person you are or what you are capable of.

Another reason why I am speaking English is this: I am familiar with phrases such as: green with envy, yellow with jealousy, black with despair, red with rage. Do you think like that? If so, what are the colours that you see in this conversation? In what colours would you paint that conversation? You may say you are not painters, but it is very important for you to know who or what you are. That is one reason why we advocate that people should have an analysis in order to get accustomed to who they themselves are. It is very unlikely that you have discovered that yet. So although your tendency may be to say you don't paint, I say you do. Therefore, get out your colours;

don't write notes about this story, make some marks on paper. Use a few simple colours like blue, black, yellow, green. Then look at it; there you will get an idea of how that patient struck you. If you were a musician, what piece of music would you compose? If you were a writer, what language would you choose? French? French as it is spoken in Paris, or the Midi, or the Touraine? So, listening to the conversation between yourself and your patient, what language is being talked, either by him or her, or yourself, or both of you?

Q: It is interesting to note that in French we say, "Yellow with envy" rather than green.

Bion: That is why it is so important to know not what language is spoken in France or England – these geographical boundaries are not of importance when it comes to a question of the mind or character or personality – but to borrow the language of painters, musicians and so on, and to use it in this extraordinary subject with which we are concerned.

Q: Do you think we are able to choose the vertex?

Bion: Yes, and the more you know about yourself, the more you know which vertex to choose in order to look at the problem. For example, looking at this man who I have tried to describe, would you choose him to go mountaineering with? Would you choose him as one of your team in the Tour de France? Never mind about psychoanalysis or psychiatry for the moment – is there anything you would choose him for? Whether we like it or not, the choice is an arbitrary one because analysis has to be done by each of us alone – it is a lonely occupation.

We have become used to the idea that psychoanalysis is an attempt to make a scientific approach to the human personality. It is a view which attaches great importance to facts, to the truth, to the real thing. If that is so, there are plenty of people who are scientists without that official categorization. A painter, for example, may believe that a painting should be true to truth, should show you some aspect of reality which you might otherwise not notice. He is not a psychoanalyst, but he paints a picture. Look at this picture and then you may see what a tree or a face looks like. If an author writes about imaginary characters like Falstaff, Lear, Othello, Macbeth, they ought nevertheless to remind us of real people. Does the last scientific article

that you read in the *International Journal of Psycho-Analysis* remind you of real people, or doesn't it?

Q: Are you suggesting that the analytic experience can be a dehumanising one?

Bion: I think that there is a great danger of it. I come across a lot of what is thought to be scientific psychoanalysis, but it doesn't remind me of anything except boredom.

The situation in the consulting room, the relationship between these two people, could be like the ashes of a fire. Is there any spark which could be blown into a flame? In this little bit I have described, we would have to examine, observe, devote care to mental debris – bits of what we have been taught, bits of what we have learnt, bits of what the patient has been taught. In analysis one is seeing the totality of debris. What has happened to the face of a man of forty-two? Why does he look twenty-five or sixty-two? Why does he say he is forty-two? It is all part of the debris. Do those pieces come together? Would you be able to put them together so that they make sense?

Q: [*an inaudible reference – to "psychotic experience"*]

Bion: The idea that it is a psychotic experience is very cerebral. In analysis we are concerned with something which might ultimately be expressible in cerebral terms, but that is not how it appears to us as practising analysts. That is one reason why we have to reconcile ourselves to the fact that patients do not come to us with little labels tied to them saying, "manic", or "depressive", or "manic-depressive", or "schizophrenic". If they do come with such labels we should regard them as more pieces of debris. I do not mean by calling it debris that it is not worthy of attention; I mean that it is something which has to be observed and scrutinized with very considerable care, otherwise you might throw away the necessary, vital spark. One cannot afford to cast aside imaginative conjectures on the grounds that they are not scientific – you might as well throw away the seed of a plant on the grounds that it is not an oak or a lily but just a piece of rubbish. This applies to all that goes on in your consulting room. But I suggest that it would be worthwhile considering it not as your consulting room, but as your *atelier*. What sort of artist are you? Are you a potter? A painter? A musician? A

writer? In my experience a great many analysts don't really know what sort of artists they are.

Q: What if they are not artists?

Bion: Then they are in the wrong job. I don't know what job is any good because even if they are not psychoanalysts they need to be artists in life itself. A mathematician can see that an algebraic formula is a beautiful one; a musician can hear a manuscript which is simply black marks on paper. Even using the language I know best, I cannot tell you what an "artist" is; I prefer you to go beyond that word and see what I am trying to convey to you by this very inadequate word. It is certainly not somebody who is able to deceive your eyes, to make you think that there is a tree there when there isn't one, but somebody who has made you able to see there really is a tree there and its roots, even if they are underground. I suggest that behind this forty-two-year-old man is hidden a person, and that person has roots, an unconscious which, like the roots of a tree, is hidden from sight. There are not only branches which are ramified and have veins, but under the surface it has roots. So when this person comes into your room, what do you see? I am not asking simply what do you see with your eyes, but also what does your intuition enable you to see?

Q: When you relate the roots of the tree with the unconscious, do you have an image of something that can be experienced as roots of the unconscious, or the unconscious as roots?

Bion: No. "Unconscious" is simply one of these words invented by Freud in an attempt to draw attention to something that really exists. But, as usual, one gets caught up in the word, and then there are these interminable, wearisome – to me – arguments about Kleinian theory, Abrahamian theory, and all sorts of theories. I cannot be interested in them because they obscure the fact that there is, as far as I am concerned, actually such a thing as a human mind or personality. I don't believe that anybody has yet discovered how that human character or personality is to be described, although a really good portrait painter can paint something which shows not just the colour of the skin or the shape of the person. An artist in England painted a portrait of Winston Churchill. His wife hated it so much that she destroyed it. And yet plenty of people thought it a very

fine portrait. The artist, Graham Sutherland, was not a psychoanalyst, not in that category, that box, but was he an analyst or wasn't he? Similarly, you might say to me, "Ah yes, but I'm not Cézanne, I'm not Sutherland". I don't want to flatter you, but all I can say is, how do you know that you aren't? Have you been to your *atelier* and discovered what sort of artist you are?

Q: Would you say something about what you have described as a catastrophic situation.

Bion: The word "catastrophe" has also to be understood in the light of something which goes in the opposite direction. I think of it as "breaking down" which is very close to the metaphor, "breaking up". In an analytic situation, the analyst is concerned with trying to make conscious, trying to bring to awareness, something which the patient has often spent his life trying to make unconscious. There are two people in the room who come together at the same time, in the same place, but the directions in which they are thinking are different. They could agree if the analyst consented to become very disturbed and afflicted with the same kind of neurosis or psychosis as the patient, but it is usually supposed that the analyst should not lose his capacity for being aware of the world of reality, although he may be drawing attention to a world of a different form of reality. The simplest example I can give is this: we are in the state of mind which is usually known as being awake or conscious and aware of what is taking place – so we think. But when we are asleep we are in a different state of mind. This division into day and night is not very illuminating, but I think it is useful if one can retain the valuable quality of being able to go to sleep, as well as the valuable quality of being able to wake up. That "marriage" often seems not to be harmonious. For example, patients may admit that they had a dream but they don't take it seriously; they don't feel disposed to tell you where they dreamt and what they saw. They say, "Oh, I just dreamt it"; I don't know why they "just dreamt it". If the acorn said, "Oh, they're just roots", what would one think? After all, even an acorn on an oak owes something to the roots. So what is one to make of a patient who thinks he "just dreamt it"? Freud considered that dreams ought to be treated with respect; I think that is the most important part of his work, but I don't believe we have got anywhere near to reaping the consequences of treating dreams with respect.

Q: [*Questions about the meaning of the terms "breaking down" and "breaking up". There are no direct equivalents in French*]

Bion: What does the patient say to you when he thinks he is "going mad"? You have to find out from the patient what it means. When he says he is breaking down, presumably that is what a breakdown looks and sounds like. You don't have to believe that the patient's diagnosis is correct, but you can look at the picture yourself which he calls "breaking down". You then have a chance of using your senses to tell you what this word means and also what language the patient is talking. It is no good saying he is talking French or English – that is too clumsy.

Q: Is it the specificity of the language which develops in the "*atelier*"?

Bion: Yes, and the specificity of what the analyst does. Cézanne's pictures of the Montagne Sainte Victoire are not the same as mine would be if I took photographs of it. What is the difference? You have to look at the paintings to find out; they are the only language Cézanne could speak to convey to me what I ought to be able to see if I look at that mountain. Your patients are not really very good artists, but they do usually know what it feels like to feel their feelings. When they try to tell you, they haven't much of a vocabulary. So you listen to what they say and look at what they are, compare the two and then form your own conclusions about whether they are – to use the English language – breaking up, breaking down or breaking through.[1] The patient is usually describing something which I am sure exists – mental pain. When it is physical, you can ask, "What sort of pain is it?"

With the kind of patients that we have we need to be able to recognise the different names which are given to pain: anxious, frightened, terrified, embarrassed, ashamed, and so forth. They are all different varieties of pain. If you were trying to paint them you would have to use different shades of colour, but psychoanalysts have to invent the language. Our material is not visible, it is not palpable. Sometimes a patient doesn't seem to be able to communicate and wants to hold your hand, to have a physical method of communication. Most

[1][Bion drafted a rough sketch of a paper with this title in 1975 to use for a talk given to members of SCOLA on 9 December 1975, but he did not complete it. See footnote on p. 61. *Ed.*]

analysts restrict themselves to verbal communication, but that is only a recently discovered method of communication – not a very good method, but the best we know.

Q: I recently had a patient who didn't feel it was necessary to talk in order to communicate with me.

Bion: Such patients don't really understand the possibilities of verbal communication. They do understand the possibilities of being able to evacuate their urine, their faeces, and even their breath. So when they talk they are aware of the muscular activity of expulsion, not the mental quality of thinking.

Q: That confirms my experience with this patient. Once he was frightened about a friend called Pierre. He thought he was very hard [*inaudible sentence . . .*] similar to throwing stones out of his mouth.

Bion: It is very difficult to get any impression unless you are with the patient. One possibility is that he is impressed by muscular movement. In that way he would be afraid that he would either lose some part of his personality if he spoke, or he might injure the analyst with these stones; he could say things which were very hurtful, rude things, insults. Even – a rational conjecture could be – that he is afraid that if he is spontaneous or natural he will say insulting things which would make the analyst very angry. When this patient talks to the analyst, what aspect of himself is being expressed? Could he be aware of the growth of renal calculi [kidney stones] long before anything showed in X-rays or in physical palpations? As well as the more accepted ideas of our response to the free associations of the patient, there can be this complication: a bodily symptom, a chemical symptom, the formation of calculi, shows up earlier in the mind than it does in any other way. The question is, what are you to say to the patient? How do you transform your thoughts, feelings, ideas about what is presenting itself to you into a verbal language which the patient would understand and which would also be correct. It is a very tough problem, and I see no way of answering it unless you are in your consulting room.

Q: I wonder if it is what happens with children as well . . . [*inaudible passage*]

Bion: It is difficult to know where the origin of the pain is. Children today are often acutely sensitive to what is going on; they know a great deal about their schools, their teachers, the town or city or country that they live in. But it is not the same thing we know as grown-ups. So when they tell you something, you can be reasonably sure that their information is very acute but their experience is not great; they have not lived long enough to be able to understand what their knowledge or their senses tell them. It may be perfectly natural for a child to be loyal to its contemporaries and not therefore want to pass on information to somebody who is of a different generation. So there is a division which is not simply between one's unconscious and one's conscious, although it is similar to that; it is a division between what the child reminds you that you once were with what you know you are today. You may have forgotten that the child you were was loyal to other boys and girls and did not tell your parents things you knew and didn't regard as dangerous, because you did not have enough experience to know they were dangerous. So you have this problem which is partly to do with yourself, partly to do with the actual child who comes to you, but is also concerned with what I have described as "the vogue". I am not talking about the mode, just a passing manifestation of the vogue, but the vogue itself: that force which exists, always exists and is very powerful.

I feel that we have left the interview with the man of forty-two for rather a long time. Here we can discuss the problem at considerable length, but not in the consulting room. The question is, why does he remind me of a young man of twenty-five? And why, as I look at him, does he remind me of a man of sixty-two? At this point I wonder if he has any children. Would they make him older or younger? I think I would like to see him another day; I might then find out whether he is married or not, or if he and his girlfriend have produced children.

I am used to the idea of mental conflict, but are there physical conflicts? Can a person look twenty-five and sixty-two at the same time, but not forty-two? What bodily muscles are being used? Some of them are vocal cords, but what else? What about his skin? What about the lines or the lack of them on his face? How is that done? Do we as psychoanalysts have to be aware of physical as well as mental conflict? I recall one patient who was always very co-operative, and after a time – probably after too long a time, I'm afraid – it became clear to me that he was the only patient who didn't disturb the

appearance of the couch; when he left, it was almost as if nobody had lain on it. Then it occurred to me that he lay in exactly the same place every time he came. That made me think that it was a sort of catalepsy, mental catalepsy. I could never honestly say he had a dream; I could never honestly say he was awake; he was between the two. He wasn't unconscious; he wasn't conscious. How did he live in such an exact state of mind? Physically he could lie in exactly one position on the couch: now it became clear that he was doing the same thing mentally.

Q: There are two points I would like to raise. First, here in Paris there are complaints that there is no discussion about the choice of patients. Second, I have been told several times that patients want to stop analysis but their analysts don't want to wean them.

Bion: I would fall back on an expression I find useful, borrowing a term from the mathematicians: "absolute initiative". By "absolute" I mean in either direction – initiative to go back; initiative to go forward. The important point is the initiative, not the direction. That seems to me to be very close to something fundamental and basic, even physically, almost like the functions or the impulses which are born when the adrenals become active, making it possible to fight or run away, to run into the danger or away from it. I say "initiative" to give this neutral spot in between the two. Who gives birth to a child? The mother, or the full-term foetus? Does the full-term foetus in some way indicate that it has had enough of being in the mother's inside? Or does the mother indicate that she has had enough of carrying that load with her? That is putting it in pictorial terms. Let's start again. Does the patient want to see the analyst, or does the analyst want to see the patient? I think the cataleptic situation does represent a sort of refuge; you don't do either.

The other day I heard an interesting account of a patient who seemed to mention the Fourteenth of July. He apparently said quite a lot, but nothing about the Fall of the Bastille or the people dancing in the streets celebrating the holiday. That seems to me to be rather like looking at an X-ray in which you can see the lungs, but why is it hazy in this part? Why can't you see the ribs clearly? What is the matter with this story? While you are looking at this debris, as I call it, you also need to be aware of what is wrong with the story that you are

being told. What is missing? You have only heard the beginning and would almost certainly have to see the patient again. But when you do that, you are also starting analysis and you may discover that you don't want to go on with that patient, but that patient *does* want to go on with you. You have to be aware of that possibility at any moment. The same thing applies in your *atelier*: you may not have decided what sort of artist to be, but as you see what you are fairly good at, you may have to "make the best of a bad job", as we say, and decide to find out what you can do with what you have in your *atelier*.

It is very important to be aware that you may never be satisfied with your analytic career if you feel that you are restricted to what is narrowly called a "scientific" approach. You will have to be able to have a chance of feeling that the interpretation you give is a beautiful one, or that you get a beautiful response from the patient. This aesthetic element of beauty makes a very difficult situation tolerable. It is so important to dare to think or feel whatever you do think or feel, never mind how un-scientific it is.

APPENDIX

"Vitrail", by José-Maria de Heredia [1842–1905]

Cette verrière a vu dames et hauts barons
Étincelants d'azur, d'or, de flamme et de nacre,
Incliner, sous la dextre auguste qui consacre,
L'orgueil de leurs cimiers et de leurs chaperons;
Lorsqu'ils allaient, au bruit du cor ou des clairons,
Ayant le glaive au poing, le gerfaut ou le sacre,
Vers la plaine ou le bois, Byzance ou Saint-Jean d'Acre,
Partir pour la croisade ou le vol des hérons.
Aujourd'hui, les seigneurs auprès des châtelaines,
Avec le lévrier à leurs longues poulaines,
S'allongent aux carreaux de marbre blanc et noir;
Ils gisent là sans voix, sans geste et sans ouïe,
Et de leurs yeux de pierre ils regardent sans voir
La rose du vitrail toujours épanouie.

This window saw great dames and barons high,
Sparkling in mauve and gold, in flame and nacre
Beneath upraised right hand that makes the maker
Abate proud coifs and crests, and prostrate lie.
Then forth, to hunting-horn or trumpet-cry,
Falcon on fist, or falchion slung and saker,
Towards plain or wood, Byzance or St. Jean d'Acre,
Course or crusade, as hawks at herons fly.
Now castellans and chatelaines repose,
The greyhounds couchant at their pointed toes,
Prone on the dalles in lozenged white and black;
Sans speech, sans sight, sans semblance, in the tomb!
Only blind eyes of stone the rays flash back,
Hues of the Rose forever in full bloom.

TWO PAPERS:
THE GRID AND CAESURA

1971/1975

'The Grid' and 'Caesura' were based on talks given at meetings of the Los Angeles Psychoanalytic Society in April 1971 and June 1975, respectively. *Two Papers: The Grid and Cæsura* was first published in 1977 by Imago Editora, Rio de Janeiro. A revised and corrected edition was published in 1989 by Karnac Books, London, by arrangement with Francesca Bion and Mark Paterson.

Two Papers

The Grid and Caesura

THE GRID

The Grid is an instrument for the use of practising psychoanalysts. It is not intended that it should be used during the working session.

The left-hand vertical column is an indication of categories in which a statement, of whatever kind, should be placed; this category indicates developmental status.

The horizontal axis is intended to state, approximately, the use to which the statement is being put. The two axes should thus together indicate a category implying a comprehensive range of information about the statement. It has been considered useful to include two rows for β- and α-elements neither of which are real or observable. The β-element row is for the categorization of elements like an unpremeditated blow which is related to, but is not, thought. The next row, C, is intended for categories of thought which are often expressible in terms of sensuous, usually visual, images such as those appearing in dreams, myths, narratives, hallucinations. This category will certainly require extension as psychoanalytic experience accumulates; even now it deserves a 'grid' of its own to expand it suitably for psychoanalytic use.

The use of the remaining categories may become clearer as the paper progresses but it may be as well to anticipate comment on rows G and H. These rows can hardly be said to have any approximation in reality. G is supposed to await the development of psychoanalytic deductive systems, and H the equivalent of algebraic systems. It is to be hoped, as always, that they will not be prematurely developed, for premature development can become as tiresome an obstacle to progress as post-maturity-blindness to what might already be seen to be available for practising or theoretical psychoanalysts.

Row F is intended to represent a category for statements, formulations which already exist. In it can be placed psychoanalytic theories, scientific but non-analytic theories, so called laws of nature and other constructs already accepted by various disciplines as being at least temporarily acceptable as genuine attempts to formulate scientific observations.

The horizontal axis is supposed to fulfil the same scheme with regard to the 'use'. The first column is for definitory hypotheses, however primitive, however sophisticated – as expressed by the row in which it is thought fit to place it or them. About these it may be worth observing that they always presuppose a negative element, that is to say, if I say this paper is about the Grid *that* is what it is about, *not* cookery or measurement etc. Equally, however erroneous my claim may be, however obvious it is to someone else that it is about measurement (or cookery or anything else) their formulation is not relevant to this discussion, or any discussion for which the definition has been formulated by the protagonist. Its falsity or otherwise is a function of its relationship to other elements in the scheme. Thus, if, 'we shall leave at sunrise', is stating a definitory hypothesis about the hour of 'our' departure, it is incontrovertible and the fact that an astronomer would consider it to be astronomically incorrect, or a theologian that it is a statement betraying 'hubris', does not controvert the definitory hypothesis. This is my definition of a definitory hypothesis, and as a definition it is a dictate not subject to alteration. The rest of the paper and the various ways in which its elements can be categorized can, however, be criticized as incompatible with the definitory hypothesis.

Column 2 resembles row C in that it requires expansion into a 'grid' of its own. My original idea was that it would supply a series of categories for palpably false statements, preferably known both to the analysand and the analyst to be false, but it was soon evident that it would be necessary to consider what the lie was to be used for, and it was evident at once that 'lie' was a question – begging and possibly misleading term. I remember Melanie Klein saying in the course of a private conversation (and it was a view she expressed more than once) that liars were impossible to treat. I could see that it is a terrible handicap for a psychoanalyst, who depends on being correctly informed, to be habitually and consistently incorrectly informed. I suggested, however, that it could possibly be a form of

deep disturbance which was betraying its presence by that form of operation – indeed her theory of projective identification could itself be presented in the course of analysis as a series of lying statements. It became evident that a distinction would need to be made between a lying statement and a false statement, the false statement being related more to the inadequacy of the human being, analyst or analysand alike, who cannot feel confident in his ability to be aware of the 'truth', and the liar who has to be certain of his knowledge of the truth in order to be sure that he will not blunder into it by accident. In short, it was evident that once again the 'use' to which a statement was being put is an essential feature of the practising psychoanalyst's appreciation of his evidence as it unfolds before him. To leave the problem for the time being, it is simplest to consider column 2 as relating to elements known to the analysand to be false, but enshrining statements valuable against the inception of any development in his personality involving catastrophic change. At this unsatisfactory point the discussion must, for the present, be left.

The columns 3, 4, 5 are relatively simple; column 3 approximates to Freud's idea of memory and notation as he describes it in his paper on Two Principles of Mental Functioning (1911b). Column 4 comes closer to attention – free floating with column 5 as more directed to some particular object. The psychoanalyst who is devoting his attention to arranging his schedule has his attention directed to a particular; a patient dominated by feelings of suspicion will likewise be devoting his attention to particular persons or things. Columns 3, 4, and 5 may be conveniently regarded as a spectrum of attention ranging from memory and desire to floating, general attention to a further extreme of particularity. A good example would be the experience of the psychoanalyst when he attends to material seeming to support a theory such as the Oedipal, or the patient seeking to refute or confirm a suspicion that he is admired.

Column 6 is intended to categorize thoughts which are closely related to, or are transformations into, action. This category, like row C and column 2, is one which soon illustrates the difficulties inherent in trying to evolve an instrument which might assist a psychoanalyst to clarify his thinking about his psychoanalytic problems. I wished to find some category in which I could place acting out. At first it seemed helpful but it took very little time to demonstrate its defects. Indeed, I can say that an early casualty in trying to use the Grid is the

Grid itself. Nevertheless, its use has made it easier for me to preserve a critical and yet informative, illuminating, attitude to my work. In this respect it has, as far as I am concerned, served a useful purpose which has made me think that others might find it profitable to invent and apply a grid system of their own; in time someone may evolve a more generally acceptable system and proceed from that to the formation of grids suitable for particular types of difficulty, different disciplines and perhaps different nationalities.

The first difficulty to be cleared up is what relationship column 6 bears to row A (β-elements). The intention is to include a category which is not thought at all. Just as it can be argued that Descartes himself in his concept of philosophical doubt failed to doubt the necessity of a thinker – an omission which I have been convinced should be repaired by psychoanalysts – so I think psychoanalysts should entertain the reciprocal belief in personality without thought. In the practice of psychoanalysis it is well known to everyone that patients will often say they 'have no thoughts', or are 'thinking of nothing'. It seems to me that the usual supposition that resistances or denials are operating are theories which have so often proved their value that it would be dangerous, to say the least, to suppose anything else without convincing evidence. Yet I am certain that the psychoanalyst should at least be open to conviction. The existence of a β-element row appears to leave room for such convictions if it should prove useful to entertain them. The column 6 category is intended for something which by contrast is thought, even though it is thought apparently instantaneously transformed into action, or, to reverse Keats's formulation of Negative Capability, 'action which is used as a substitute for thought and not action which is used as a prelude to thought'. Keats, it will be remembered, speaks of the capacity for tolerating half-truths and mysteries as essential for the language of achievement in contrast to thinking as a substitute for action. This differentiation of row A from column 6 seems potentially to be a useful aid to assessment of psychoanalytic experience provided it is used in situations other than the session during which analysand and analyst are engaged in psychoanalytic practice. As with row C, the column 6 categories could themselves be extended, using a grid system for that category itself. The uses to which I put the Grid, which I shall now illustrate, may serve as more effective than further explanation.

First, I will give some examples of row C constructs which I have chosen because they have a vivid pictorial quality; they are well known and the first is Freud's own famous choice, *the Oedipus myth.* 1
As it is well known I do not propose to take time on it except to stress the part played by Tiresias and the Sphinx in addition to the characters usually regarded as constituting the central feature of the story – the old King, his Queen Jocasta and Oedipus.

In the *Royal Cemetery at Ur,* approximately 3500 BC, the King was 2
laid to rest. As far as the scene can be reconstructed from the excavations carried out by the joint expedition of the British Museum and the Museum of the University of Pennsylvania, included in the ceremony was a procession of the notables of the monarch's court into a specially prepared pit. There, clothed in the splendour of their jewels and finery they took a potion of a narcotic drug, conjectured to be hashish; to the accompaniment of music the pit, with its occupants in position, was then filled in with earth.

The site chosen for this cemetery was the city's refuse heap. We may assume that the magic performed that day was held to have sanctified the ground chosen and thus to have overlaid not only the real rubbish deposited on that site but also the view, if it existed, that the human remains were rubbish and that the appropriate place for the disposal of rubbish was the rubbish heap. Sanctification made the ground desirable for those who sought a resting place of magic property for their own dead rubbish. Thus the sanctified place, together with the sanctity which made it desirable, came in the course of time to lose its virtue as it became vulgarized, too full for further burials, and finally reverted to its former use.

Some five hundred years later a different kind of procession took place at the same site. Unless psychoanalysis develops a technique analogous to that of archaeology we shall not know what was in the hearts and minds of those courtiers of Ur, Abraham's City, when they walked into that death pit, took their potion and died. It may be easier to guess what was in the minds of *the plunderers* who became so 3
active during the Third Dynasty. Five hundred years was not long in those days and the mental climate in which that court, with its wealth about it, chose to accompany its king cannot have been so completely dissipated that the tomb robbers could be without fear that they might meet the spirits of the Dead in the course of their adventure.

The Royal mourners demonstrated the power of Religion, Ritual, Magic, Drugs. The plunderers demonstrated the power of gain, and we should perhaps accord them a high position in the Pantheon of Scientific Fame as the forerunners of Science in the domain more usually left in the possession of Magic, Religion and the Dead.

This reconstruction is a transformation of the archaeological report on the joint expedition to form the verbal counterpart of two visual images, burial and plunder. For convenience I transform burial to A; plunder to B. I propose to use the two images A and B to represent the entire domain in which it is usual for psychoanalysts to operate. The visual images represented by A and B impose a degree of rigidity and immobility on the elements composing the pictures. If we disarticulate the images, the elements composing them are freed and the patterns become incoherent elements on which one can impose a pattern which makes order appear where none existed before. The facts worth attention are those which introduce order into this complexity. I have done this by introducing a five-hundred-year gap which separates these two facts in a relatively meaningful way: order has been introduced though it may not seem to add much to what is known. The fact which I have introduced is an idea of dividing the elements into two – those occurring in say 3500 BC and those occurring in 3000 BC. Separating the elements, dividing them into two categories or sets labelled respectively 3500 BC and 3000 BC may make the elements meaningful.

It is possible that that categorization, effected by introducing an idea of time as the instrument by which the separation and selection is effected, yields a train of thought of this kind: how powerful must be the force, emotional, cultural, religious, which can impose on a group of people a course of action certain to lead to their death, without their apparently being deterred by what is so certain. Is there any equivalent force in operation today which could obscure or conceal a fact as dangerous to us and as apparent to our posterity as the death of the men and women who proceeded into the death pit appears certain to us? A child can do something as dangerous to its life: are we correct if we assume it is ignorance? Would we be correct to assume that it is something unknown, more dynamic than ignorance which impelled it on a course certain to lead to its death? Is it the ignorance of the childhood of the race which is amply sufficient to explain the death of the Royal Court of Ur? Or is there some force for which we

require a name – like 'religion' – because 'ignorance' is not pointing or denoting a sufficiently dynamic force?

Reciprocally, should we regard the 3000 BC group as demonstrating the power of a prospect of wealth to overwhelm the fears of the tomb robbers? As I have said, the space of five hundred years would then be scarcely long enough to dim appreciably the fears of the forces which had led to the death march of the ancient court. What courage would be required to brave those murderous forces – or was it simply a love of gain? How did the robbers come by the knowledge which enabled them, five hundred years after the event, to sink the shafts into the earth with such accuracy as to find the Queen's Tomb? Was it luck? Should we regard our religious hierarchy as spiritual descendants of the priests of Ur? Should we erect monuments to the plunderers of the Royal Tombs as Pioneers of Science, as scientific as our scientists? Or should we consider today's scientists as deserving of obloquy for their cupidity?

The A group seem to have each taken a narcotic drug before they were buried alive. Was that the only drug, conjectured to be hashish, or was there some much more powerful force, more deserving of the title of 'drug', which was operating even before the death of the monarch?

What was the drug taken at B? Was it curiosity? When we consider the hostility attributed to the deity both with regard to the Tree of Knowledge in the *Garden of Eden,* and expressed by the confusion of Tongues in the myth of the building of the *Tower of Babel,* the question becomes significant. This and other points will be discussed further when we consider omnipotence. 4 5

The five stories, numbered in the margin, constitute a verbal picture gallery. They provide me, with such few additions as I pick up from my general reading, with models for almost any aspect of the emotional situations I can see for myself in that domain where practical psychoanalysis and psychoanalytic theories intersect.

The Ur reconstructions are based on those of Sir Leonard Woolley: I think they conveniently adumbrate the whole emotional domain with which psychoanalysts have to deal in romantically primitive and therefore compressed terms. [Historical writers, reconstructing what Freud calls historical truth for lack of psychoanalytic history, have to leave out the people – Hamlet without the Prince. *See* Sir Frederick Powicke, *The Lord Edward*.]

In addition to the five stories mentioned I include the *Death of Palinurus* (Virgil, Aeneid Book V) [see page 29].

Religious formulations which divide good and evil do not possess the significance of the undivided principle residing in the same deity. In the practice of psychoanalysis I am convinced that the emotional experience can be discerned as a constantly changing pattern of emotional experience. If the psychoanalyst develops his capacity to intuit these experiences he can become aware that there are certain experiences which are constantly conjoined and that these constant conjunctions are themselves experienced as repeated conjunctions. These constant conjunctions become manifest to the psychoanalyst after a period of time (provided he resists an irritable searching after certainty) as a sensuous kaleidoscopic change; the sensuous change will bear a resemblance to elements of the C categories that are found amongst his models.

I am aware that it may seem that I am suggesting that the psychoanalyst should engage painfully on the elaborations that he then strives to match against his emotional experience in his sessions. This is directly contrary to fact. His own analysis should have put him in reach of denuding himself of his memory and desires. The formation of his own private battery of C category sensuous elements – myths, images and so on – is carried through away from any psychoanalytic session, though it may be genetically related to his work sessions. Once formed it does not matter how often and how variously he re-forms these C-category elements provided he conforms to the discipline of denuding himself of memories and desires and, as soon as he can, of his tendency to understand. Darwin expressed one aspect of this discipline when he stated to his wife (as she reported in the appendix to his autobiography) that "it is fatal to reason whilst observing, though so necessary beforehand and so useful afterwards". The opacity of 'understanding' and its plausibility as an aim of the psychoanalyst tend to hide the danger of precocity and prematurity.

The more the Grid, or something more effective, is studied, the clearer will it become that the psychoanalyst will not only have to develop his power to intuit but he will need to keep it in good repair in the way, analogously, that the eye surgeon must keep the small muscles of his hands in perfect order. It is useless to have an armament of theories and to be insensitive to the facts which have to be

interpreted. Classical, Kleinian, or other theories present no difficulties in practice. The psychoanalyst is aware of Freud's principle that matters which are observed must be called by their proper names. If he witnesses certain facts he is under an obligation to state his evidence; equally, he must not report what he does not see. Otherwise he is guilty of fraud.

For the purpose of this communication I propose to give a factual account of a one-time patient who attended regularly for a psychoanalytic course. I categorize it as a fairly sophisticated account; so I label it F3. The man had, I understood, an academically successful career until he left school and joined a commercial firm as a research chemist with good prospects and a safe job. An admiring relative was going to pay the fees. He was well acquainted with psychoanalytic circles and had slight knowledge of me but I did not know how much. He lay on the couch and lapsed into silence. I waited and after a few minutes asked him what he was thinking about. He did not reply. I became aware after a further silence that he was not in fact being silent – he was stammering. Of course, I thought, I should have realized that; he had told me he had a stammer which sometimes became so intense that for a period he could not say anything. I listened intently. (It was directed attention so I call it column 4 row B? row C?) He would breathe deeply, pause, let out his breath and start again. Each time he would draw in his breath suddenly and sharply and then suddenly let it out again as if experiencing considerable relief. I could make nothing of it. After a few moments he became silent again.

After a further pause I realized I had been listening in the expectation that he would speak and not listening to what I could hear. At first my impression was that he was straining to pass a motion. Again he relapsed into a silence. This time it was broken by sounds as if he were swallowing, perhaps nearly retching. I drew his attention to the facts and said that they could, if I ignored all impressions other than sound, be evidence of activity at both ends of his alimentary canal. He agreed verbally but as if the 'stammer' continued; as nearly as I can represent it he breathed out sharply "Hah, hah, just . . . hah . . . a problem . . . hah . . . hah . . . in ph . . . huh. . . her . . . nation." I said he seemed to be making both a sarcastic comment on what was taking place – his 'stammer' and my interpretation. He then said, after

a preliminary check in his voice but not in his lips, "I think you are quite right." Fear of further difficulty made him talk hurriedly, stop quickly as if exhausted and remain silent.

In this brief account of one part of one session I shall assume that the narrative is as nearly truthful as I can make it. I do not make notes in a session or afterwards so that it is open to anyone to object that the account cannot be true. I am sure it would be even less true if mechanisms had been devised which seemed to record and repeat whatever was to be thus preserved (F3). But I have already categorized my attention to the patient as being suitably represented by category F4. Either the categories are badly drawn up and unsuitable for the load I am trying to make the Grid carry, or my assessment of the material is faulty or, more likely than either, both are true. Anyone who examines the Grid both on psychoanalytic grounds and for scientific methodological rigour will be dissatisfied. Too much must not be expected of human beings attempting discipline with a method which is hardly a hundred years old. J. O. Wisdom has been critical, but rightly appreciative, of Guntrip's attempt to bring methodological standards to bear on psychoanalysis. As I am not able to offer any suggestions for improvement I shall leave the unsatisfactory formulations alone and comfort myself that I am resisting the temptation to reach irritably 'after fact and reason' through my not being 'capable of being in uncertainties, mysteries, doubts'.

The most striking feature of the episode was the discovery of the extent to which I began to feel the futility and exasperation of sitting waiting for a man to tell me what he wanted when he would not speak at all. This was almost at once followed by astonishment that apparently he could not talk – that his stammer was so severe. I felt no wiser and no nearer to thinking of any interpretation which was likely to have the effect which I had always understood good interpretations to have. One of my colleagues once told me he had given the patient all the interpretations known to psychoanalysis without any effect whatever. Allowing for exaggeration I could sympathize with his feelings. Today they are my familiars, but two points help – these feelings are no longer strange to me and I do not quite so easily allow myself to be deafened by the uproar of what the patient is not saying or doing. The danger is not that some possible interpretation known to psychoanalysis is not known to the overburdened psychoanalyst, but that he is so distracted by particular instances masquerading as

the discovery of a new general theory that he cannot observe the facts. Although I have now for many years devoted myself to the practice of analysis, as opposed to talking about it, I am constantly surprised by the extent to which I fail in this apparently simple and yet rewarding task. In fact, it took me a very long time to become convinced of the need to denude myself of memory and desire, and longer still before I appreciated the vicious effect on observation that was exerted by a need to understand. The latter is a particular instance of the obtrusion of desire which is liable to rationalization by psychoanalysts. It may be as well to mention some features which contribute to the difficulties of any psychoanalyst disposed to try this discipline. It appears to be easy. It is contrary to the conventions of ordinary medical practice to be unaware of so many and such apparently important items in the family and individual history, and it would leave the psychoanalyst open to attack on the grounds of negligence should something go wrong. The mass of evidence which becomes available in contact with the personality of the analysand makes it necessary to tolerate the constant oscillation from paranoid-schizoid to depressive position, or from patience to security which I suggest as more accurate descriptions of the psychoanalyst's fluctuations.

The resolve not to allow myself to be distracted by the facts about the patient which I did not know, but thought I might be expected to know, proved a great, though at times guilty, relief. I soon extended the procedure through all my practice, always, it seemed, with advantage. I cannot describe the process in detail, though with regard to the Grid I found the thought required, whether to satisfy myself, which I did not succeed in doing, of the soundness of my estimate of what had taken place, or to effect some improvement in the Grid as an instrument, itself led to a great clarification of my thinking both generally and with regard to the particular patient with whose problem I was concerned. This advantage, like others, did not quickly become clear to me. The gradual and imperceptible nature of the progress contributes to the difficulty in my knowing how to proceed in order to pass on the nature of the experience to colleagues. Being wise after the event, it surprises me how often the attempts to clarify my experience would lead to the emergence of what seemed a bright idea and how often the bright idea failed to materialize in practice. At first I was outraged by this and wanted to distort the evidence to conform to my hunch. This breaking of my own rules was always a

failure and contributed to a sense of fraudulence. It took some hardihood and misery to say goodbye to any of my brain-children. I was hardened in my resolve to do so by the discovery that the bright idea shared the quality which is displayed in a dream when it appears to disappear not so much bit by bit, but completely and as a whole. It was at about the same time that I realized that the same idea could reappear as suddenly and as completely. I hoped that full attention to the analysand would act as the trigger which would start off the forgotten, but hopefully appropriate, thought. None the less it is a sad thing to have to abandon one's bright ideas before ever having discovered how bright they were.

I am concerned here to write some of the thoughts stimulated by this and other sessions round about this time. This is not so much a report – the kind of event which I would categorize by column 3 – as a reverie *now* about the kind of reveries I learnt to indulge in these early days of psychoanalytic practice. The effect of my own analysis was that it diminished the obstructive force of unconscious memories and though I acquired new ones, usually believed to be the theories of my analyst, the effects of such recently acquired memories were of a different kind from those usually characterized as inhibitions; these last could be more fruitfully, though more vaguely, described as column 2 categories – that is to say, psychoanalytic objects feared as liable to trigger off developments of a catastrophic nature, to initiate 'catastrophic change'. Their nature may well be exemplified by two descriptions which cannot possibly be described as psychoanalytic.

The first is that in which Poincaré, the mathematician, describes, in his *Science and Method,* the psychological accompaniment of elaborating creatively a mathematical formula. I shall not quote it again because I have already quoted it so often as to risk pushing it towards becoming a ritual, a recital in scientific terms of a formula intended to keep at bay the development, in today's cant terms of the political dictator, of 'dangerous thoughts'.

The second is a quotation from the autobiography of Max Planck of a discovery which was only incidental to his work with mechanical quanta. "It is one of the most painful experiences of my entire life that I have but seldom – in fact, I might say, never – succeeded in gaining universal recognition for a new result, the truth of which I could demonstrate by a conclusive, albeit only theoretical proof. . . . This experience gave me also an opportunity to learn a fact – a remarkable one

in my opinion: a new scientific truth does not triumph by convincing its opponents and making them see the light, but rather because its opponents eventually die, and a new generation grows up that is familiar with it."

After I had discovered in the course of my work with all members of my practice, the obstructive quality of preconceptions, the patient's analysis became more lifelike. It did not matter whether the preconceptions had sprung from what I had consciously and unconsciously gathered from the contact with the patient, or whether it was something I had heard in another context, or whether it was some psychoanalytic theory. The increase in lifelike quality was associated with an increased readiness to perceive non-verbal quality. As I became more practised at ignoring – or as Freud put it, "artificially blinding myself" – certain memories and desires, I found the patient's attempts to speak less able to demand my attention. There he lay, spluttering and farting and sucking away with his lips, and never a word of English. Had he been in command of the knowledge one would expect of a man of his age, I should say it was a perfect symphony concert of rude noises. It was, had I realized it earlier, a virtuoso performance. For some time I made interpretations appropriate to the idea that the noises were being made by a single mouth but I could be aware, in the course of my daily cogitations – the occasions for which I had elaborated the Grid – that this idea was related to an assumption that a personality corresponds to the visible anatomical structures of the person. There used in my childhood to be a character known as the one-man-band. With an arrangement of pulleys, strings, a drum and a sort of harmonium he could be kicking up his heels, waving his arms, throwing his head back violently and suddenly, and thereby putting up a tolerable imitation of a musical performance, sounding his drum with his forehead, ringing a bell with his occiput and so forth. For some reason I could not understand, I was not allowed to watch this performance but used to be hauled off as if from some indecent spectacle. I was reminded of this – another model for ephemeral purposes – as I dragged myself into contact with the patient. After a time I said it sounded as if his mouth, his anus, his throat, were all engaged in a struggle for attention, for who should be supreme. "Fff . . .", he replied, "F.f.f . . . Ffphonation" , he finally exploded. "It sounds" he said with increasing freedom "as if they were trying to settle who was top. But. . ."and again he became inarticulate. For a moment or two

he repeated noises which I was quite used to hearing. The pattern of sound was very distinct but though I felt sure it resembled something I was still unable to suggest any further interpretation. I said, "These different parts of the anatomy seem each to have a personality, like a real person, and each to be ambitious to make use of your "phonation"". "Like trying to get hold of the microphone and keep all others out", he said. I thought of 'internal objects' (F4) but could not see that this theory met the difficulty of which I had been vaguely conscious before when speaking of what was to be considered as marking the boundaries of the personality. I could not feel sure that the patient felt that these 'objects' were inside him. As he was speaking they might as well have been 'outside' him. I asked him if he felt they were outside. He continued easily and fluently about a companion of whose intelligence he had very great doubts. He said he was afraid he might have to work with him as his partner on an explosive project and that might be extremely dangerous. Once before, a man had caused an explosion in the laboratory which seemed to fragment every glass vessel in the room. They might both have been killed. As it was, his companion had lost an eye. He did not want to lose his. He stopped, leaving me somewhat surprised by such a long speech. There was no sign of impediment; nor could I see any impediment to the expression of a copious flow of interpretations which was occurring to me. I would have been reduced to stammering myself if I had even tried to formulate them. I said he was expressing his anxiety about having to come for an analysis to a psychoanalyst whose intelligence was as limited as my own. Compared to Doctor X, a very good psychoanalyst whom he knew, I was felt to be about as intelligent as a bottle compared to a breast. "Contrariwise", he interrupted. I then said he felt the bottle to be at least efficient compared with the human being with whom he shared the laboratory. I said the envy with which the eyes regarded the intercourse had led to an explosive destruction of the eye and the glass vessels. He began to stammer again and there was no further verbal communication. The session ended but not before I had noticed that this time no sound came from his lips. The movement of his lips was most pronounced and most peculiar. As far as I could see from my position it was as if the muscles of the mouth were fibrillating in a way which I have known only in heart muscle and associated with the lipidoses. I could not see how this effect was

produced. Though I was for a number of reasons suspicious of this patient and was careful not to allow symptoms to escape notice, I did not see this symptom recur. However, it alerted me to the necessity for watching for transformations of problems of personality into systems with which they are not usually associated. In so far as developments of either one's own or the analysand's outlook can be traced to certain nodal events (in fact I am convinced it cannot), it forms a convenient fiction which may be used for separating one part of a discussion from another.

I have gathered together my cogitations on this and other cases which I was psychoanalysing at that time without a temporal or spatial framework. A problem which seemed to be insoluble, or to be assumed to be solved by being linked to an extremely inadequate solution, was that presented by the liar. Having had experience of the creations of someone who was in fact notorious enough in his capacity as a liar to be known diagnostically as a pathological liar – a diagnosis that begs all the questions but becomes more manageable if it is regarded as a definitory hypothesis (D, E, F1) – I found I had to respect what, had he been a writer of fiction, would have been regarded as great gifts of imagination. The situation became more complex when I found it necessary to give papers, write reports and teach. What a gift, what a blessing I thought it would have been to be a born liar! No sooner had I thought it than I realized that I was deploring the lack of the one characteristic which is in fact inborn though it had to wait, as always, for the genius to reach its full capacity. In this case the genius, or group genius, who invented speech released the liar from his bondage. The point was brought home by a veterinary surgeon who, on being asked whether it was not a great handicap to have patients who could not say what they were complaining of, replied that it was made up for by the fact that they could not lie either. My stammerer was on certain occasions in that position: he lacked the gift of language! And even when he could talk his whole prejudice was to speak the truth. I did not at first realize the handicap under which he laboured when, as was often the case, he wished to preserve a private life *and* have a psychoanalysis. For convenience, the assumption of priority of deception as the senior function, has some value for emphasizing a possibility usually disregarded. In fact I claim no value for this idea other than that of drawing attention to

one of the inherent problems of psychoanalysis. Communication, not even verbal communication, was designed for the purpose of psychoanalysis as a method of scientific investigation of the personality. Many methods of investigation, religious, legal, philosophical, have been elaborated for the discovery of truth. The lot of psychoanalysis has been to expose the hollowness of the pretensions of all these disciplines. As far as possible we need to find some method by which we do not fall into the same pit. At the outset there is a difficulty – for we do not purport to dictate, even suppose we could, how anyone can be made to use psychoanalysis for scientific purposes only. Anyone is free to undergo a training and, once qualified, use his qualification for any purpose he chooses. The analysand can persist in courses of action which led to his original departure from health and which will inevitably undo any growth which psychoanalysis might promote. The patient I have selected as a point of discussion was one who by training, ability and prejudice was particularly likely to pursue his analysis to develop his scientific flair.

I shall begin with the choice of two apparently different types of liar. One I shall call the 'charming' liar, the other the 'poisonous' liar. The terms have an advantage in being known in conversational English and are usually reserved for people who symptomatically are very different. This superficial difference soon tends to declare its superficiality. Both are peculiar in the significance they share socially. Indeed, a phrase which has come into use recently shows that the presence of both psychological trends operates in the very highest circles to such an extent that an almost scientific term has had to be invented, namely, 'the credibility gap'. The chief reason why these trends need to be recognized is because they appear to have, borrowing a biological term, a toxic effect on mental development. I am not speaking only of individual mental development, though that is naturally the central concern of psychoanalysts, but the mental or psychological or moral development of whole groups. This is not the place to discuss the group aspect of this problem but I think psychoanalysts will ignore this extension of the individual to their peril. But . . . why did my patient stammer? Certainly I would have been hesitant about regarding him as falling into either of the two named categories. He was mischievous in a pleasant way, he was kind and considerate. He was the victim of much cruelty, a fact of which he was unaware and for which I was dependent on hearsay.

As the analysis proceeded I was able to interpret the stammer as part of a dramatic presentation of three people in the room. The most obvious trio was of course Father, Mother, Child. The closest representation of this depended on the actual session. I have found no way in which it is possible to pass on to someone who was not there the changes constantly occurring in the sessions as a whole or those occurring in any single session. Naturally psychoanalytic colleagues would like to have evidence; naturally I would like to give evidence. But with the passage of time I am convinced that there is no substitute for psychoanalysis.

The following is an attempt to indicate the direction in which evidence is to be found. Let us assume that the psychoanalyst has managed to rid himself of the clamour of psychoanalytic gang warfare, the pressures of the daily problems of individual survival, to a point where it is relatively quiet in the office. The man of whom I am writing was often speechless for very considerable periods. As I have already indicated, my preconceptions – now I would call them my psychoanalytic and other prejudices – made it difficult for me, as it was for him, to tolerate the silence. As I became more able to silence my prejudices, I also became able to be aware of the evidence that was there rather than to regret the evidence that was not. As my ears became used to the silence, little sounds became easier to hear. I was reminded of an analogy which Freud used where he wrote of having artificially to blind himself in order to direct the faintest glimmer of light in a very dark situation. Transforming this I used the analogy to consider the importance of 'artificial silence' in order to hear very 'faint noises'. It worked. I began to hear sounds which would formerly have passed unnoticed.

My object in giving these accounts is their value in providing verbal formulations of visual images. The visual image, as television and the movies have shown, has great power of lateral communication. Verbal communication, or at least the written form, depending on the durability of the medium, has greater staying power, as witnessed by the Homeric poems, the code of Hammurabi, Virgil and, in recent times, Shakespeare. When it comes to phonation (it will be remembered that when my patient did vocalize he did it with great accuracy and precision and used that term) the situation is more complex. Tacitus gives a good general description of the function of the bard in the Germanic tribe; he also gives particular descriptions of the

part played by Percennius after the death of Augustus Caesar. Should you wonder what this has to do with psychoanalysis, I suggest that you let your curiosity lead you to listen to recordings – I was able to study some which I borrowed from the British Broadcasting Corporation – of Hitler's speeches made at rallies in Nürnberg. The emotional forces active in the time of Tacitus are still active. I am fortunate in not understanding German and therefore was not distracted by the element of articulate speech to a point where I could not hear the phonation or be unaware of the *β*-elements. I define these as elements which lie outside the spectrum of 'thought'.

The dilemma for the psychoanalyst is this: I do not believe, and nor does anyone else who has had close contact with men in battle conditions, prisoners of war or civilians in similar stress, that the feelings of men and women either as individuals or as members of a group have changed; they are dormant. Often they are covered by a veneer of civilization which, however, does not conceal though it may disguise the forces beneath. Sometimes it becomes clear to the psychoanalyst that the boundaries of the person do not correspond to the person' s anatomical structure. Melanie Klein, as I understood her to say, did not think that there was any mystery about apparently concerted movements in a group of analysands beyond what could be explained by transference relationship with the same analyst. I think we should keep an open mind. I do not feel any need to postulate 'extra-sensory' perception, a herd instinct as Wilfred Trotter did, or a group unconscious as Jung did. I think, however, that there may well be some analogue in the personality to the capillary blood system which in ordinary conditions is dormant but in extraordinary conditions may dilate as in surgical shock. The analogy would be such hyper-stimulation of the individual 'groupishness' that his capacity for conscious, sophisticated behaviour seeps away into his 'unconscious'. Freud considered that there might be substance in Weismann's theory of the individual personality as subordinate to the germ plasm (1915c, page 125). There are certainly situations in which the analysis seems to be on the periphery of the main theme: the investigation continues but it is difficult to suppose that the field being investigated is of real consequence; yet the patient comes, though he complains of the futility of the procedure. The complaint suggests awareness of some preoccupation which is not futile. If the patient were a child who goes to a parent and asks, "What shall I

do now?" it would be easier to understand. But he is not a child and the psychoanalyst does not purport to suggest solutions for such problems. Why then does the analysand behave as if he were? It may be that the analysand has developed, the psychoanalyst has developed, and the problems have developed the fastest of all – so fast that they have outgrown psychoanalysis itself. That is a guess but there are others. I do not limit myself to one 'favoured' solution. Freud may have been on the wrong tack, or, as I think more likely, man, even Freud, cannot possibly do more than scratch the surface in the short time available to him. There is also a possibility that the training, the teaching, is both too good and too bad. It is so good that it becomes second nature to go and find some expert to work out the problem. It is so bad that all initiative, all capacity for finding out is destroyed. The problem, the object of curiosity, has to be approached symmetrically. 'Too good' and 'too bad' is not a formulation of a conflict; it is a formulation of a symmetrical relationship. It is analogous, in the domain of personality, to bifocal vision in the domain of visual inquiry. In sensuous experience the eyes are focused, brought to a point where they 'meet'. The 'apparatus' of intuition cannot be expressed in the simple terms available to formulation of homogeneous sensuous experience. Real and imaginary only supplement each other when they do not meet, when it is known that two parallel lives in the domain of sensuous experience meet, but in the domain of personality they become symmetrical.

Freud's second thoughts about using the term 'interpretation' when 'construction' would appear to be more apposite is certainly compatible with, though I could hardly regard it as confirmatory of, my idea that for some purposes for which analysts use interpretations they require constructions, and that these constructions are essential instruments for the demonstration of symmetry. A sensuous component of this apparatus is the visual image. The C elements I have sketched out differ from the interpretation, which is usually monovalent, whereas the construction (C element) is polyvalent and is faster than the F or G formulations though it may not be faster than the H formulations if and when they can be discovered. This is a matter of great practical consequence when the psychoanalyst has to cope with primitive material. The analysand operating on a primitive level comes close to acting on the principle of 'act first, think later'. Usually the analysand in such an episode is acting in relationship with

the analyst as if, to put it in a mixture of real and imaginary terms, an extremely active, flexible and speedy unconscious were being pursued by a slow, rigid, lumbering conscious.

I must now take up in some detail a word I often use, in common with most psychoanalysts – 'analogy'. I have in fact used analogy in describing the conscious as lumbering after the unconscious. I used it without acknowledgement because the form is disguised (revealed?) as a silent metaphor; its use is disguised. Sometimes the metaphor has become so much a part of conversational English that it is 'dead' – unless, as Fowler points out, it is brought to life by juxtaposition with another metaphor whose inappropriateness, non-homogeneity, sends a galvanic-like flutter through it. As I have already pointed out, confusion can occur because attention is given to the two images used in the analogy, and not, which is the important point, the relationship between them. Vaihinger exaggerated the relationship, not surprisingly, into a philosophical system.[1] Freud spoke of this contribution in *The Future of an Illusion*. Bringing to bear the construction, the polyvalent weapon of symmetry, I would suggest that we need to consider the future of an analogy, the future of an 'illusion', the future of 'transference' which is the name given by psychoanalysts to a particular and potent form of relationship. If one could arrange the term, spectrum-wise, in ascending power of emotional drive it could be: generation → analogy → transference → delusion illusion group illusion → hallucination → asymmetry → degeneration. C elements are used to provide anchorage for the relationship – mouth is one anchor, breast is the other. Both of these terms have been treated as if they were the essential features of the analogy. It is exactly this point that marks the divergence of the path of growth from the path of decay. The breast and the mouth are only important in so far as they serve to define the bridge between the two. When the 'anchors' usurp the importance which belongs to the qualities which they should be imparting to the bridge, growth is

[1][Hans Vaihinger (1852–1933), a German philosopher influenced by Arthur Schopenhauer and F. A. Lange, developed Kant's thinking by putting forward a theory of 'fictions' as the basis of what he called his 'as if' philosophy. His major work, begun in 1876 and published in 1911, was *Die Philosophie des Als Ob* (The philosophy of 'as if'). Vaihinger's ideas informed Bion's work on the value of analogies and of mathematical thinking. *Ed*.]

impaired. The man with the stammer was 'held' because he could not progress beyond the importance of defecation, urination, the mouth as an object to be sensuously gratified by the tongue and vice versa.

The interpretation or construction produced by the psychoanalyst depends on the intuitive link between analysand and analyst. As it is constantly imperilled by deliberate attacks, its essential frailty and ordinary fatigue, it needs to be protected and maintained. The object of the Grid is to provide a mental gymnastic tool. It can be used in relative isolation from attack and cannot do harm so long as it is not allowed to intrude into the relationship between analysand and the analyst as by the elaboration of some theory about the patient which is then stored up and used as something which can be discharged like a missile in a battle.

What I have said of the function of the anchors in an analogy will show how acute the attention needs to be. The point is emphasized by certain patients whose sending and receiving of signals depends on the use of a very narrow waveband. The message sent by the analyst is either correctly metred or it is not received. Similarly, the message sent by the analysand has to be received by the wide-band receiver as represented by symmetry. I have experienced this in its most acute form in the musician who has perfect pitch. I have also had to contend with it in a patient whose visual sense made it impossible for him to tolerate the slightest deviation from what was, in his opinion, the correct colour.

These facts require that the analyst should not allow himself to be restricted simply to the evidence provided by speech, but must he be restricted to the communication? Freud said it is better to avoid 'symbolic disguisings', but what about symbolic revelations? It may be the only kind of reception which is commensurate with the child's ability. Analysands often think they can afford an analysis. If the figures add up correctly according to the rules of their religious belief in the omnipotence of money, and if the power of financial rituals to control their anxieties are commensurate with their anxieties, they may be betrayed into an entirely erroneous belief that they can 'afford' a psychoanalysis.

Freud shows that while he regards belief in God as an illusion, he has no doubt about the reality of the illusion. The illusion must be taken seriously by psychoanalysts. In this particular sphere I think *interpretation* (as opposed to construction) of omnipotence

is particularly unfortunate. It minimizes the constant conjunction which is the reality that is often so inadequately represented by the single term, 'omnipotence', or even the symmetrical version of it, 'omnipotence–helplessness'. The Palinurus story [see below] (which I think Virgil intended us to take seriously as part of religion and not just an epic poem, any more than Milton regarded *Paradise Lost* as an exercise in artistic virtuosity) provides a better 'construction' than any 'interpretation' or other invention to draw together the conjoined elements when 'omnipotence' is in question. The liar gives substance to his phantasies of omnipotence because, unlike speaking the truth, he does not simply record – he does something. Recording, speaking the truth, is merely to be an insignificant cog in the machinery. In effect this means that in the personality in which intolerance of frustration coexists with great ambition, greed tends to dominate and the 'result' dominates the greed. The 'end', or 'aim', or 'supposed aim', of an activity precipitates prematurity and precocity. It is difficult to accept real life because frustration is an essential feature of real life. In an extreme position it obstructs the development of thought. As Freud points out, the capacity for thought acts potentially by interposing delay between an impulse and its transformation into action, but it can also make the frustration, inseparable from translating thought into action, more bearable. The 'ambitious–intolerant conjunction' can then perpetuate itself; thought being replaced by omnipotence (which has no part in reality) tends thus to increase frustration, denies the personality such moderation of frustration as thought might provide, and impels towards violence such as robbery and murder. The premature acquisition of the supposed valuable object means that even a genuine valuable cannot be used to yield satisfaction because the maturity required to effect the transformation from potential to actual is missing. The term 'omnipotence', as contrasted with 'construction', such as the Palinurus story, is too abstract to give an idea of the reality to which the psychoanalyst attempts to draw attention. Omnipotence–omniscience–god, together with the symmetrical elements, helplessness–incomprehension–agnosticism, are the abstract statements of the basic group. I shall now introduce, instead of these abstract terms, the C version, a verbal formulation of a visual image.

THE DEATH OF PALINURUS

The anxieties of father Aeneas being allayed by Neptune, the fleet takes advantage of the calm following the storm; it is ordered to conform to the movements of the column steered by Palinurus.

The sailors go to sleep. Somnus seeks out Palinurus bringing the guiltless man bad dreams. Disguised as Phorbas he seats himself on the stern and proceeds to seduce Palinurus by pointing out that it is time for sleep, the seas are calm and favourable and that he, Phorbas, will take over the tiller allowing Palinurus to rest. Palinurus makes a very direct and contemptuous reply, scorning the suggestion that he would sleep when dealing with such a treacherous sea, or risk the life of his commander. He does not let go the tiller or take his eyes off the stars by which he steers.

The god then shakes the dews of Lethean forgetfulness over him and hurls him into the sea with such violence that Palinurus carries part of the stern with him. His comrades do not hear his calls for help and he is drowned.

Aeneas, finding the ship yawing, and saddened by the fecklessness of Palinurus, takes over the helm.

This model is one from which, according to the dictates of the material, the analyst can formulate a 'construction'. Interpretation, in the sense which Freud discards the term, may indeed be a useful preliminary, a prelude to the 'construction'. The symmetrical nature of the story makes possible the choice of any element to be the vertex, without alteration in the value of the function. Thus, the patient might be obtruding an anxiety about drugs; the analyst is offered a choice of drugs in this story. A patient may wish to obtrude a grievance about unfair treatment; again, the analyst has a choice of elements on which his attention might focus. The point I make is that the story helps to draw attention to the fact that certain elements are constantly conjoined; that fact may escape attention but for a model of this kind. The gap between the theory and the patient on the couch can be too great for relevance to be apparent, especially when the prejudice in favour of theory is too active. Equally, if there are not enough C models, the lack of theory may mean that the structure is not strong enough to carry the load it has to bear in practice.

The respect in which psychoanalysis seems to me to be seriously deficient is in models (C) of omnipotence–helplessness (F). As a result the constantly conjoined elements are recognized as isolated units which have relevance only on rare occasions and fail to stimulate a response when they should on occasions which are of more frequent occurrence. The deficiency may be more apparent than real. If the Eden and Babel myths are used for models for the omnipotent–helpless theme and reinforced by the riddling Sphinx of the Oedipus myth, the deficiency is lessened. The 'morality' of the deity may also be expanded by consideration of the views expressed in Chapter 2 of the *Bhagavad Gita.* Such models help a psychoanalyst to bridge the gap between a theory and the material which is manifest in the psychoanalytic experience.

It is assumed that the psychoanalyst considers that the sophisticated theoretical formulation (F) and the model (C) are legitimate transformations, each of the other. In other words, there are invariants present in the psychoanalytic experience and in the theoretical formulation. On the correctness of this assumption the genuineness of the psychoanalysis depends. I have described elsewhere that under projection a round pond and an avenue of trees on the ground can be represented by an ellipse and two converging lines on a piece of paper. In short, there are invariants in these two factually different objects – the pond and trees, and the drawing. What are the invariants if one object is the fountains of Rome and the other the score of a piece of music by Respighi?

I have given a summary in visual terms of Virgil's account of the death of Palinurus. What are the invariants common to this and to the stammerer on the couch? What are the rules which have to be obeyed if the analysand can reasonably be expected to understand the analyst and vice versa?

In the world of physics an orchestral performance appears to be transformable, given suitable apparatus, into wireless waves; these can be transformed back again so that another human being can assume he is listening to an orchestral performance. Can a modern English-speaking person be trained to understand the printed representation of Virgil, Aeneid, Book V, lines 827–871? Can a trained person intervene between the Latin formulation and an American in such a way that there is a carry-over of invariants common to the Latin poem and the English comprehension?

I cannot, even if I wanted to, answer these questions. Nor, as far as I know, can the Grid. But I have found, and think that others might likewise find, that the Grid could serve to provide a mental climbing frame on which the psychoanalyst could exercise his mental muscles. Even its defects could be turned to advantage.

Ezra Pound has been severely criticized for his translation of the classics such as his *Homage to Sextus Propertius,* the *Analects of Confucius,* and the *Classical Anthology.* It could easily be shown, perhaps too easily, that Pound was guilty of certain schoolboy howlers in his translations from the Latin. Since he is a human being there is no shortage of human frailty available for ammunition, the symmetrical approach being adulation and abuse. The practising psychoanalyst, the portrait painter, the musician, the sculptor, all have to 'see' and demonstrate, so that others may see, the truth which is usually ugly and frightening to the person to whom the truth is displayed. In the same way the ugly and frightening are usually believed, by the person to whom they are displayed, to be identical with the truth.

℘ It takes a genius, a Faraday, to demonstrate the reality of electricity so that people of less messianic capacity can understand so much that they can switch on an electric light.

It takes a mystic to demonstrate the existence of God so that people who lack that endowment can understand enough to know when and how to switch on the appropriate ritual and employ the correct magic.

It takes a Freud to demonstrate the reality of emotional resources to such a point that people who have not such capacity can nevertheless receive the communications which demonstrate the resources and make them available.

So-called Scientific Laws are vulgarizations of that which the scientific mystic can achieve directly. Religious dogmata are similarly vulgarizations of that which the religious mystic can achieve directly.

The function of the Establishment, Scientific and Religious, is to protect the mystic from destruction and the group from the disruptive effects of the mystic. The Grid, like a primitive scheme of electrical switches, wires and so forth, is intended to help preserve psychoanalysis from being destroyed 'in its infancy', and

> the group, which has the misfortune to harbour such a lusty child, from disintegrating as a result of the uncontrolled and undirected vigour of the infant. As is the way with infants it can impress its environment both with its power and helplessness. ♁

The total description between ♁ and ♁ is by way of a pictorial simplification, and therefore an inevitable distortion, of the facts to be represented. Either the description becomes, like so much mathematics, indistinguishable from a meaningless manipulation of symbols, or it gains in psychological digestibility at the expense of scientific vigour. Psychoanalysis has not reached a point where it can be communicated without the presence of the objects which have to be demonstrated. In short, the object being interpreted, for which the construction is being elaborated, must be present at the time when its presence is supposed to be made manifest by the 'construction'. A microscopist cannot be constructing his microscope while he is looking through it – though he may be adjusting his powers of observation to its defects. The Grid is to be used in the process of this period of preparation, not as a substitute for observation or psychoanalysis but as a prelude to it.

CAESURA

SOURCES

S. Freud, *Inhibitions, Symptoms and Anxiety*.

> There is much more continuity between intra-uterine life and earliest infancy than the impressive caesura of the act of birth allows us to believe.

M. Buber, *I and Thou*.

> The prenatal life of the child is a pure natural association, a flowing toward each other, a bodily reciprocity; and the life horizon of the developing being appears uniquely inscribed, and yet also not inscribed, in that of the being that carries it; for the womb in which it dwells is not solely that of the human mother.

V. C. Walsh, 'Preface' to *Introduction to Contemporary Microeconomics*.

> If one leaves a happy, spirited discussion with friends about currently debated topics . . . to get down to the job of arranging introductory lectures on the subject for a large audience, one may be struck by a certain oddity. The two worlds seem to have no intersection.

M. Buber, *I and Thou*.

> Every developing human child rests, like all developing beings, in the womb of the great mother – the undifferentiated, not yet formed primal world. From this it detaches itself to enter a personal life, and it is only in dark hours when we slip out of this again (as happens even to the healthy, night after night) that we are close to her again. But this detachment is not sudden . . . like that from the bodily mother.

M. Buber, *I and Thou*.

> From the glowing darkness of the chaos he has stepped into the cool and light creation without immediately possessing it. . . .

S. Freud, Letter to Lou Andreas-Salomé from *Letters of 1873–1939*.

> I know that in writing I have to blind myself artificially in order to focus all the light on one dark spot. . . .

St John of the Cross, *Ascent of Mount Carmel*.

> The memory must also strip itself of all those forms and kinds of knowledge, that it may unite itself with God in hope.

S. Freud, Letter to Lou Andreas-Salomé from *Letters of 1873–1939*.

> . . . renouncing cohesion, harmony, edifying effects and everything which you call the symbolic element. . . .

M. Buber, *I and Thou*. (Reference to Jewish myth).

> . . . in his mother's womb man knows the universe and forgets it at birth.

St John of the Cross, *Ascent of Mount Carmel*.

> . . . the love which the memory always has for other forms and kinds of knowledge which are of supernatural things, such as visions, revelations, locutions and feelings which come in a supernatural way. When these things have passed through the soul, there is wont to remain impressed upon it some image, form, figure or idea, whether in the soul or in the memory of fancy, at times very vividly and effectively. Concerning these images it is also needful to give advice lest the memory becomes encumbered with them and they be a hindrance to its union with God in perfect and pure hope.

The foregoing quotations were made from the vertex of different disciplines, at different times and in different languages. They delineate the universe of discourse within which this paper is confined.

Psychoanalysis is concerned with the domain of ideas; included are thoughts and feelings of all kinds. Although it could be described as a limited domain, a limited human activity, its scope nevertheless is vast when one considers *all* thoughts, feelings and ideas which are presented to us in the course of our work. In the physical sciences the human being is dealing with a physical material: psychoanalysts are concerned with characters, personalities, thoughts, ideas and feelings. But whatever the discipline there is a primitive, fundamental, unalterable and basic line – the truth. "What is truth?" said jesting Pilate, according to Francis Bacon, and would not wait for an answer. *We* probably cannot wait for an answer, because we have not the time. Nevertheless, that is what we are concerned with – inescapably and unavoidably – even if we have no idea what is true and what is not. Since we are dealing with human characters we are also concerned with lies, deceptions, evasions, fictions, phantasies, visions, hallucinations – indeed, the list can be lengthened almost indefinitely.

In our relationships with analysands time is limited and choice inescapable. Which, of all the right interpretations, are we to choose to formulate? The analyst's freedom, though great, can be seen to be limited, at any rate on one boundary, by the need to be truthful, to give an interpretation which is a true one. If the analysand is sincere in his wish for treatment he likewise is limited; his free association should be as near to what he considers to be the truth as he can get. The course of the discussion itself between analyst and analysand may make it more possible to assess the degree of truth or falsity in

any particular idea which is under scrutiny. But is one to call a feeling 'an idea'? It is a matter of definition, but we cannot exclude feelings any more than ideas from the field which we are to survey.

The embryologist speaks about 'optic pits' and 'auditory pits'. Is it possible for us, as psychoanalysts, to think that there may still be vestiges in the human being which would suggest a survival in the human mind, analogous to that in the human body, of evidence in the field of optics that once there were optic pits, or in the field of hearing that once there were auditory pits? Is there any part of the human mind which still betrays signs of an 'embryological' intuition, either visual or auditory?

This may seem to be an academic and unimportant matter – unless we think that there may be some truth in the statement made by Freud that there is some connection between post-natal thought and emotional life, and prenatal life. To exaggerate the question for the sake of simplicity: are we to consider that the foetus thinks, or feels, or sees, or hears? If so, how primitive can these thoughts, or feelings, or ideas be?

Events sometimes take place in the consulting room, where there are present only myself and a grown man or woman, which suggest feelings that I could describe as envy, love, hate, sex, but which seem to have an intense and unformed character. It is convenient to fall back on physiology and anatomy to borrow ideas in order to express my feelings about some of these events; to think of some of the feelings which the patient is expressing as being subthalamic, or sympathetic, or para-sympathetic. There are occasions when the patient mentions some anxiety, fear, or a symptom (like blushing) briefly and unobtrusively, yet in a way which suggests that something is being mentioned in disguised and feeble terms because it is the best that the patient can do to give effect to feelings which are feared for their intensity, magnitude and obtrusiveness compared with those feelings which most people are used to regard as normal. Similarly, the patient may express a fear of the future which has many of the characteristics of a past which one thinks he could not possibly remember; nor can he remember the future because it has not yet happened. These things, so faintly expressed, may in truth be very powerful. I can imagine that there may be ideas which cannot be more powerfully expressed because they are buried in the future which has not happened, or buried in the past which is forgotten, and which can hardly

be said to belong to what we call 'thought'. If you apply pressure to your eyeball you can see, in response to the physical pressure, what appears to be something which could only be a response of the optic apparatus. If that is so then maybe the optic pits respond to pressure even before the dramatic caesura of birth itself. From the point of view of the analyst the fact that the analysand is a grown man or woman can be so obtrusive, the evidence of the eyes so obtrusive, that it blinds him to feelings which are not so clearly presented to the optic apparatus.

Any attempt to classify the material with which we have to deal should be regarded as provisional, or transitive; that is to say, part of a process from one thought or idea or position to another – not a permanency, not a halting spot at which the investigation is ended. When the analyst is not sure what it is that is obtruding he is in the position of having an intuition without any corresponding concept – that intuition might be called 'blind'. Any concept, for example projective identification, is empty when it has no content. The problem for the practising analyst is how to match his hunch, or his intuition, or his suspicion, with some formulation, some conceptual statement. He has to do that *before* he can give an interpretation. The analyst's role, in other words, is one which inevitably involves the use of transitive ideas or ideas in transit. The analysand, likewise, is attempting through his free associations to formulate an experience of which he is aware.

As things are at present, giving an interpretation means that the analyst has to be capable of verbalizing a statement of his senses, his intuitions and his primitive reactions to what the patient says. This statement has to be effective as a physical act is effective. The analysand's difficulties, already great enough, are increased by his being limited to what little he can in fact do even when able to use free associations. We have to impose limitations; the analyst could not work if the analysand were free to resort to physical violence. When a patient comes with firearms the analyst has to rely on physical alertness to deal with such a potentially dangerous situation. It is less serious when the patient substitutes a musical instrument for the gun – although some types of musical instrument can make the analyst's interpretations inaudible. One instrument that is usually available is the ability to scream. I have mentioned elsewhere the trained singer who is able to scream in a way not open to less gifted

or less well trained people, and who can thereby make an analytic session painful for the analyst.

What are we to think about the patient who does not want to lie on the couch? Is it possible that lying on a couch subjects them to physical pressures of a kind which are beyond their capacity to tolerate, or to verbalize, or to 'understand'? The analyst cannot interpret the 'sights' a foetus could 'see' if subjected to pressure on the optic pits. This is an object of research by the analyst in the course of a psychoanalysis where he has the opportunity for detailed and prolonged contact with patients. If he can also discuss differing experiences with different observers there is hope of seeing what is observed in common. It is one of the justifications for an analytic society.

There are difficulties analogous to those associated with the caesura of birth. A similar caesura seems to exist between the inhabitant, say, of the East and of the West. Some of these similarities/differences are spectacular, particularly in time; the mystics express themselves in terms which are strikingly similar although sometimes separated from each other by many hundreds of years. How is one to penetrate this obstacle, this caesura of birth? Can any method of communication be sufficiently 'penetrating' to pass that caesura in the direction from post-natal conscious thought back to the pre-mental in which thoughts and ideas have their counterpart in 'times' or 'levels' of mind where they are not thoughts or ideas? That penetration has to be effective in either direction. It is easy to put it in pictorial terms by saying it is like penetrating into the woman's inside either from inside out, as at birth, or from outside in, as in sexual intercourse. These pictorial formulations are primitive and general; they may be so general that it is difficult to see what is to be said at any precise moment – which is the analyst's problem. One cannot go back – although we talk about it in those words – to childhood or infancy. It is in the present that we have to have a method of formulation which can penetrate the barrier.

If, as I think, our constant problem is that of choice, this also involves inhibition. Thus, if I want to give one interpretation I have to inhibit other interpretations which I am not choosing to give. This is usually fairly simple because the choice is between a number of consciously entertained ideas; it is not easy when the inhibition has a pathological quality which makes it more difficult to entertain an unwelcome idea. Choice involves what some of us call 'splitting';

perhaps four or five possible interpretations must be considered. The human personality exists as a whole; we have to split that personality to formulate several possible ideas or interpretations. That I call non-pathological splitting. We have to find some method by which those particular interpretations can be put into an order before establishing which one is to be given precedence. This has to be done in a way which is not the same as talking about it 'doing' must be quicker. The interpretation has to be made at the right moment; it is, therefore, necessary that this non-pathological splitting, ordering of those splits and choice of formulation become part of a rapid and practised mind.

The analyst is restricted to what is available to him from his experience of his own life on the one hand, and to what he considers to be the facts which are unfolding in his presence on the other. In the practice of psychoanalysis the analyst has the advantage of the presence of the analysand. The possibilities are open-ended; we do not know what the analysand is likely to say or do to express himself and his character. The analyst is dependent on such facts as are made available to him while the patient is present and available for observation. What the patient does away from the session cannot be known to the analyst; hearsay evidence is fallacious and of small value in comparison with the direct evidence.

An infant can show a startled reaction to certain forms of stimulus. On the other hand there are stimuli which are consciously more striking to us as adults, but which pass the infant by. In an obstetric ward a baby will show no signs of awareness of the slamming of a door although it is obtrusive to the adult observer. In analysis the analyst likewise has an opportunity of observing certain reactions which are 'slight' but may, nevertheless, be of significance and therefore worthwhile bringing to the patient's attention. These trivial movements or noises show up clearly with the patient who is virtually inarticulate or silent, in contrast with the prevailing silence. This kind of experience is difficult to convey to a non-participant; it is one of the problems of communication with colleagues who, however experienced in analysis, cannot be familiar with the experience that the analyst has with a *particular* analysand. No terms – 'autistic child', 'psychotic', 'borderline' – are of much use because the experience in an analysis is more subtle, detailed and difficult to divide up into these somewhat crude divisions available to us when we borrow from the practice of medicine, or existing philosophies, or analytic theories.

Since analysis takes place in time, the tendency is to believe that when the patient is talking he is describing a state of affairs that is also 'ordered' in time; patient and analyst are liable to think of something as having happened in the past. This obscures the fact that we exist in the present; we can do nothing about the past. It is, therefore, seriously misleading to think as if we dealt with the past. What makes the venture of analysis difficult is that one constantly changing personality talks to another. But the personality does not seem to develop as it would if it were a piece of elastic being stretched out. It is as if it were something which developed many different skins as an onion does. This point adds importance to the factor of the caesura, the need to penetrate what is recognized as a dramatic event like birth, or a possibility of success, or a breakdown. The patient has a breakup, or breakdown, rather than a 'breakthrough'. Many a façade has been saved by the misfortune that has made it a successful ruin.

I do not wish to abandon the idea of the conscious or unconscious; the existing theories are valuable, when properly used, either for thinking about a situation or for illuminating the situation for the sake of someone not-self. These ideas that we hear in the course of analysis have at some time been interpretations though now free associations. We are dealing with a series of skins which have been epidermis or conscious, but are now 'free associations'.

The ability of the analysand to take advantage of the possibility of success which has opened out is a symptom of the penetration from the situation which Freud describes as intra-uterine, to the situation which is conscious and post-caesural. I do not suggest that the event is related to the dramatic episode of birth itself, but rather that that dramatic situation, if borne in mind, is easier to use as a model to understand far less dramatic occasions which occur over and over again when the patient is challenged to move from one state of mind to another. In other words, to penetrate an obstacle or layer between the states when opportunity opens out, or there is some apparently disastrous state of affairs to be turned to good account. Since we can do nothing about the dramatic or obvious external event, it provides an interpretation, later to become a free association, for the not-at-all-obvious event.

I want now to consider a non-analytic situation, namely that in which the patient has to deal with changes in his affairs by making decisions. This situation is comparable with the game of Snakes and

Ladders. The patient's choice may fall on the head of a snake and he returns to an apparently unfortunate state of affairs which he deplores and regrets; or he may arrive at a ladder and find himself in the position of being able to make several moves which are towards his final goal – which he may also regret. In either situation the choice that the patient makes compels readjustment to the consequences. Much then depends on the extent to which he is a victim of self-hatred or self-love.

The situation of the analyst is similar to that of the analysand in that he lives in a world of reality of which the analysis itself is a part. He therefore has to make choices, including the possibility of having to keep silent because he does not know an answer or cannot think of an appropriate interpretation; he can indulge himself by giving an interpretation which is only a way of passing the time.

Consider a decision which confronts most people whether to propose marriage or to accept a proposal. Either way the two people have to make a decision. I quote from Yeats's poem on this precise dilemma, 'Solomon and the Witch':

> For though love has a spider's eye
> To find out some appropriate pain –
> Aye, though all passion's in the glance –
> For every nerve, and tests a lover
> With cruelties of Choice and Chance;
> And when at last that murder's over
> Maybe the bride-bed brings despair,
> For each an imagined image brings
> And finds a real image there;

Like birth, the caesura of marriage is dramatic; it may obscure the fact that the events at the time of marriage and after are influenced by events which take place long before the marriage. As Freud put it with regard to birth, events in the patient's mind are greatly influenced by events which were in fact intra-uterine. Using this for theoretical purposes, events which are in the womb of time eventually show themselves in the conscious life of the person concerned who then has to act in the situation which has now become actual.

There are any number of different caesuras. How are they to be traversed? We must reconsider the transitive characteristic of the free association and the interpretation. Opposed to that there is what we

might call the situation at which the patient or the analyst wishes ultimately to arrive – the 100 mark on the Snakes and Ladders board. There are plenty of snakes and ladders on the way during the course of the transition from one to the other. Each free association and each interpretation represents the change in the situation which we psychoanalyse. Even the wrong interpretation causes change; misinformation in the form of false – deliberately false – statements changes the situation. How quickly can we become aware of the changed situation, and how quickly can we see what good use could be made of that changed situation even though adverse?

The likelihood of meeting old friends there makes the prospect of Hell less frightening than the prospect of Heaven for which life on earth has given no adequate preparation. But this also applies to decisions which are made over and again. One may deplore an unfortunate decision; how terrible it might be if we never made unfortunate decisions or unfortunate interpretations. In analysis it is recovery from the unfortunate decision, the use of the mistaken decision that we have to accustom ourselves to deal with. In this view of the position there is no question of a cure.

It has been said that the English and Americans have everything in common except the language. The same could be said of the analyst and the analysand; the language is apparently the one existing means of communication. Nevertheless it is also the one thing which they do not appear to have in common probably because they are talking from different vertices. A mountain viewed from different points of the compass *may* be recognizably the same mountain, but it may be such a different view that it appears to be an entirely different mountain. Consider the patient who says that he is seriously troubled by blushing, but to the view of the analyst appears to be almost invariably marked by an extreme pallor. Is it possible that the patient who rejects blushing does so by inhibiting his blood flow in such a way that he does anything but blush – the place of the blush is taken by this great pallor? I do not suggest that this is actually the case, but I think it is useful to be able to air these 'hunches' as a transitive statement on the way to an interpretation. It is important to get used to this transitive method of thinking with a view to arriving at an interpretation, which is also arriving at an immediately changing situation; whether the interpretation is correct or incorrect, fresh

interpretations will have to be made in order to meet that changed situation.

Suppose the patient does not want to lie on the couch and, having taken his place on a chair, then displays considerable restlessness and has to change to a different chair. This may be the reaction to sensations generated in the autonomic system, or from the stimulation by the CNS (in turn generated by the unpleasing sight of chair or couch). It could account for dreams of which the patient can give no account, or of which he gives a narrative account with no free associations. They would be inappropriate if he has had not what we would ordinarily call a dream, but a sense of muscular position which has reflected itself in his having a sleepless night.

Having had a dream which is in fact a sensuous experience, the patient then has to find a dream which is more in conformity with what he thinks is expected of him by the analyst. He will often betray the fact that it is not an ordinary dream by the absence of free associations. This applies particularly to a patient who is afraid that he is psychotic, or that he is going mad. He prefers to behave and speak in a way which he regards as neurotic and less severe than a psychosis. Conversely, the patient makes statements to which he attaches little importance and which he hopes the analyst may regard as unimportant; for example, the patient who complained of blushing. Some patients repeatedly state that they have some particular experience and then give the reason why – making it part and parcel of their formulation. This continued repetition suggests a state of mind which is proper to a person who only lives in a causal world. But the only world in which causes can be said to be a prominent feature is the world of *things* – not the world of people, or characters, or personalities. The patient who is always telling us that he feels such-and-such 'because . . .', is avoiding a particular relationship which exists between one character and another.

We need to re-view commonplace formulations – psychotic, neurotic, psychosomatic, soma-psychotic and so forth – to consider, from our own experience, what we think those things are when we meet them. A patient may complain about headaches together with a number of plausible explanations which are probably correct. *Rational* interpretations might be adequate if they were the only important ones, but what may appeal to the human mind because it seems to be

logical, or to fit in with such powers of logic as we have, may be by no means the correct interpretation of the factual situation which is beyond our comprehension or experience. To distort that experience in order to make it fit into such capacities as we have is a dangerous thing. On the other hand it is equally dangerous for an analyst to think that medicine, art, religion are inadequate to describe or make it possible for us to be consciously aware of the actual phenomena of reality. The analyst has to use what we hope is a non-pathological method of splitting because the total situation that presents itself to us is beyond our capacity, just as we suppose that it is beyond the capacity of the infant to have a grasp of the world as we know it as adults. It is natural for the infant to see a *part* of the world of reality; that particular view is not wrong – it is inadequate. To limit ourselves to the observation only of what we understand is denying ourselves the raw material on which present and possibly future wisdom and knowledge might depend. The fact that it is incomprehensible now, because our minds are unsuitable or ill-fitted to grasp it, is not a reason for limiting the facts such as are actually available.

It is possible that the splits in which we have to indulge as analysts, as adults, make it possible to see some things which the patient, or child, or infant can see and vice versa; they are essential to discrimination. This could be said to be one of the advantages of marriage; the two partners can, as it were, pool their defects and thereby also pool their wisdom. In analysis we are seeing a total personality who has at some time, consciously or unconsciously, chosen a particular view or a particular vertex from which to see the view. This always involves inhibition of the capacity to see the views that one does not want to see. The psychotic patient may be anxious to suppress, be blind to or unaware of what the sane person is able to see; the character is psychosis minus neurosis, or psychosis minus sanity, or sanity (rationality) minus neurosis or minus psychosis. The important thing is not that a patient is a borderline psychotic, or a psychotic, or a neurotic, but that he is a total character *minus* . . . and then we have to form our own judgement of what that patient is minus, whether the person who is almost a caricature of robust common sense and sanity is not really a character who lacks important components because he believes that a psychotic is 'mad' or 'insane', or that someone would think him insane if it were known that he had such thoughts or ideas. We could regard artists, musicians, scientists, discoverers as those

who have dared to entertain these transitive thoughts and ideas. It is in course of transit, in the course of changing from one position to another, that these people seem to be most vulnerable – as, for example, during adolescence or latency. At the same time they are vulnerable to the observation of others who cannot tolerate the totality of the human personality, and therefore cannot tolerate someone who is so 'mad', so 'curious', so 'eccentric', or so 'sane'. I remember a fellow officer in the army complaining of 'the robust common sense' of another officer. He said, "That man makes me understand why people talk about 'rude health'; I have never known a person who seemed to be so rude as he does by being so healthy". Making due allowance for the jealousy and envy which is directed towards what a person is able to be, there is nevertheless something to be said for noticing the hostility and resistance which is stirred up by the creature which is different from ourselves, or the state of mind which is different from our own, or our own state of mind which is so different from that which we like to think we can always present to our fellows.

Thus we have returned to this problem of how to transcend the caesura when one is in movement from one state of mind to another; how to surpass the various obstacles in the course of a psychological or spiritual journey of development; whether to regard those obstacles as pathological, needing pathological terms to describe them, or whether they are in fact non-pathological. In the psychoanalytic experience we are concerned both with the translation in the direction of what we do not know into something which we do know or which we can communicate, and also from what we do know and can communicate to what we do not know and are not aware of because it is unconscious and which may even be pre-natal, or pre-birth of a psyche or a mental life, but is part of a physical life in which at some stage a physical impulse is immediately translated into a physical action. That transitive experience from a passive to an active physical state may reflect itself even when we are dealing with potentially rational and articulate persons. Can we detect in these expressions of conscious rational communications vestiges of something coming from a part of the personality which is in fact physical? Sometimes we call it psychosomatic medicine; at other times it does not even become sufficiently obvious in the mental life of the patient for us to be able to detect that it is arising from an area of a person *in the present,* although it might once have existed simply primitively and

in the realm of physical action. This involves taking a different view about the obstacles to psychoanalytic progress, the development of the relationship between analyst and analysand, and considering phenomena which present themselves in the actual analytic situation, but which have not usually been interpreted – may never have been interpreted even by the patient – into terms which are communicable in the realms of articulate speech or articulate thought. I do not suggest that we can interpret something like a migrainous headache in psychological terms. This is one of the difficulties about the sort of communication which is possible in lectures, supervisions, discussions between colleagues; a supposition or hunch or suspicion, such as I make when I suggest the possibility that the fortification of light patterns which present themselves to certain types of headache really come from pre-natal levels of mind, may seem to be offering an easy explanation of something which is extremely complex, thereby interfering with, and itself becoming an obstacle to, psychoanalytic research in the one situation in which it can really be carried out – in the consulting room with such patients as present themselves for analysis. What I am putting forward as a mere suspicion or conjecture may be turned into a theory, or treated as if it were something which could be used for immediate translation into an interpretation. In so far as that is possible what I say becomes more of a liability than an asset. An analyst reading this paper must be able to forget it, to dismiss it from his mind, unless something is said by the analysand which calls it into his consciousness and causes him then to formulate it in such language as he is able to use.

Has this discussion any *practical* value for a psychoanalyst? It is a question which I fear may be provoked by my stress on practice rather than theory, not only theory of psychoanalysis but of anything – finance, political science, mathematics, painting, music and so on. The only material I have to study is a human character that can study me also and is free to walk out of my office if and when it chooses. As I cannot – within the bounds of civility and respect for facts – I must find some way of engaging the person in conversation of a kind that he might be able to tolerate while material presents itself for my assessment. A painter could estimate the quality of the canvas on which to practice his art; a sculptor might discern the grain of the wood or marble which he contemplates; the composer might allow his 'inner' eye to be impinged upon the sight, or his 'inner' ear

upon the sounds, from which he chooses to discriminate and then transforms into music. How is the psychoanalyst to transform his assessment of the person who comes to see him professionally? Into a learned article? An interpretation? A printed judgement?

Suppose the analysand begins, to all appearance, to weep. The analyst becomes aware of his own funds of compassion and is impelled to participate with caution lest his responses, like a chisel of tempered steel cutting into balsa wood, too easily fashion a pattern of which the effect could not be obliterated or corrected. The analyst is affected by the patient's tears which may trace out channels in his composure no less lasting than the excoriations which he has feared to produce in his patient. He must, therefore, be sensitive to the difference in real life – not in theory – between 'tears', and 'moisture' extruded from the bodily surface open to his inspection, both his own and the analysand's.

Rephrasing Freud's statement for my own convenience: There is much more continuity between autonomically appropriate quanta and the waves of conscious thought and feeling than the impressive caesura of transference and counter-transference would have us believe. So . . . ? Investigate the caesura; not the analyst; not the analysand; not the unconscious; not the conscious; not sanity; not insanity. But the caesura, the link, the synapse, the (counter-transference, the transitive–intransitive mood.

At this point I cannot proceed for lack of the very elements which have not yet been discovered or elaborated. It is typical of decision which has to serve the human at those junctures when knowledge is not there to be used.

FOUR DISCUSSIONS

1976

Four Discussions with W. R. Bion was first published in 1978 by Clunie Press, Strath Tay. It was reprinted in 2000 as Part Two in *Clinical Seminars and Other Works*, edited by Francesca Bion (London: Karnac Books).

EDITOR'S INTRODUCTION

These four discussions took place over the month of April 1976, at the Los Angeles Veterans Administration Hospital. What is striking in these, and all the recorded talks and discussions, is Bion's consistent preference for *addressing* questions put to him rather than answering them. However tangential or peregrinating his responses seem, they are illuminating in most cases, and in many they clarify at least the question posed.

In an unpublished 1977 paper with the ironic title 'New and Improved' (included in Volume XV), Bion expressed his gratitude to André Green for bringing to his attention the saying by Maurice Blanchot, "*La réponse est le malheur de la question*" – the answer is the misfortune (or illness, or disease) of curiosity – a quotation to which he had referred frequently. Bion was aware of how hostility, generated by the frustration and anxiety accompanying curiosity, can draw us to prefer the security of closure offered by certainty; much of his behaviour in discussion groups arose from his desire to keep questions alive and open – to the extent, in some large-group situations, of waiting in the growing silence in the hope that a Work-Group mentality might emerge to counter the prevailing culture of dependency combined with idealization.

Four Discussions

INTRODUCTION

These four 2-hour discussions at the Veterans Administration Hospital, Brentwood, Los Angeles, took place during April 1976, at intervals of one week. The group, numbering approximately twenty-five, was composed of psychiatric residents, psychotherapists, and psychologists. This edited version represents about half the original transcription of recordings of the four meetings; repetitive passages have been deleted, together with material already published.

Francesca Bion

1978

1

Questioner: I should like to hear you talk about the theory of projective identification.

Bion: I don't think there is much to be said beyond Melanie Klein's version – what she called an omnipotent phantasy; a phantasy that a person can split off feelings, thoughts and ideas he does not want and evacuate them into another person, more particularly into the mother, and more particularly still at a primitive stage of existence, namely, at the breast itself. Of course the infant doesn't *do* anything, nothing happens. But the infant *feels* as if it could do that, and *feels* that it gets rid of some characteristic which it doesn't like and then becomes afraid that that same characteristic is directed towards it by the other person – originally by the mother, or by the breast into which it projects it. The theory was not intended as a substitute for already existing psychoanalytic theories, but as an addition to them.

Q: You have used the term 'bizarre bits' to describe one aspect of projective identification. Could you elaborate on that?

B: I never intended it to be a technical term, but in discussing it with Melanie Klein I suggested that these bits which are supposed to be projected, these parts of oneself which one doesn't like, then become bits which are felt to exist, as it were, outside oneself. I think that would help to explain certain types of behaviour.

We talk about 'getting back' to childhood or infancy. It is a useful phrase, but I think it is meaningless. Do any of us 'get back' to infancy or childhood, or even tomorrow? It is clear that we don't. Why do we bother to talk about these things which, supposedly, have their origin very early in one's life? What if we do develop a character in infancy or childhood? What does it matter? Why any sort of psychoanalytic approach? The answer seems to be, and it also *seems* – how justifiably

is another matter – to be worth while bringing to light some of these alleged early developments. We could say that these characteristics which are supposedly split off, or got rid of in some way, are forgotten – and after all, we do not continue to behave like infants; apparently these things *are* got rid of. Do you remember when you were at the breast? No, it's forgotten or got rid of. But having been forgotten these things persist in some archaic way in one's mind, so that they still continue to operate, to make themselves felt. We are not aware of them although other people may be. Since they operate in this archaic way they go on affecting one's work. That is why it is supposed that the analyst has to be as thoroughly analysed as possible.

Q: When you talk about being thoroughly analysed, are you referring to bringing those things up to consciousness? What effect does a deep interpretation have – like that regarding the breast relationship?

B: The immediate reaction, from my experience, is that it is so much nonsense, a foible of the analyst. I cannot see what other preliminary reaction there can be. But after a time you begin to think there may be something in it and to be suspicious that you do behave in this peculiar manner and that therefore there is much to be said for that theoretical formulation. But to speak of a theory as if it were 'absolute truth' is ridiculous. Luckily most of us react negatively to that kind of dogmatic statement and seem to preserve our own view. The problem is how to make a statement decisively and clearly in such a way that it is possible for the other person to understand it.

Supposing there is some truth in this idea that the event is forgotten and then operates in this archaic manner, what does the individual do about it? All I can do is draw the patient's conscious attention to a view which, as likely as not, they regard as one of these things which psychoanalysts say. But if that was all there was to it, it would just stop there. We must assume that these ideas seep through; the individual is able to communicate with himself. Look at it another way: Why does the individual say he hates or fears the analyst? That is a *feeling* and if the patient says that, I haven't much doubt that he says it because he means it. If that patient has that feeling, how does that feeling seep up into consciousness to a point where it can be articulated? There must be some method of communication between these forgotten things and the conscious ability of the individual to articulate them. An infant could feel terrified or angry or hostile, but

would have no language with which to express it other than by a tantrum or a rage. In analysis it appears to be possible for people to communicate fear or hostility, or love or affection to themselves and then translate it into articulate speech – if possible even the kind of language they think the analyst understands.

To turn to another point: Is a psychoanalysis that goes on for two years, three years, four years, five times a week ad infinitum, the only approach? One hopes not. But at the same time, I haven't come across anything which is more effective, and I am sufficiently convinced of its effectiveness to want to persist in it. It is, however, dangerous to be satisfied with psychoanalysis itself; a psychoanalyst must be *dis*-satisfied with psychoanalysis. But we all hate the upheaval of revising our views; it is so disturbing to think that we might change in such a way as to feel compelled to change our partner or profession or country or society. Thus the pressure to say 'thus far and no further' sets up a resistance to learning.

Q: Confronted with a world in which all established standards have collapsed, man realizes with a sudden surge of despair that he no longer has recourse to any higher appeal. This means that he is totally free but has what Camus and Sade call 'dreadful freedom'; man must now assume the responsibility for all of his actions with no appeal to a supreme authority. "There are no longer guilty men" says Camus, "but only responsible ones." In existential thinking this has several implications. Unable to stand the anguish of uncertainty a man may lapse back into some ready-made pattern of behaviour, letting himself fall into a stereotype – religious, political, philosophical and so on. Camus calls it 'philosophical suicide'. Or a man may make a leap into faith by creating for himself a new deity as a transcendent source of appeal. My question is: When you are confronted with a patient who is vacillating between coming to terms with himself, learning to be introspective, and falling back on the quasi-religion, whether it is psychoanalysis or standard religion, how would you feel about guiding that person to self-realization?

B: I have an objection to guiding the person, because I cannot believe that I know how to conduct my own life. Many years of experience indicate to me that I am still in existence more by luck than judgement; that is the only way I can put it. Therefore I dislike suggesting to somebody else how they should solve a problem. Of course, patients ask you to do that for them, and of course you

always are doing it for them – even if unwittingly – because the fact that one turns up in the office so many days a week and expects the patient to do the same, itself suggest that that is the way to behave. And because I behave or try to behave in a particular way in analysis, the patient – like the child who is fascinated by the bad habits of the parent – is most likely to pick up our bad habits, not our good ones. It is possible that patients convert them into some sort of symptom which they then repeat until they get it right themselves – they solve the problem. A patient may learn the particular habit or mannerism – such as I have with my hands for example – but if they pick it up and repeat it, it begins to feel wrong to them; they feel that it doesn't suit *them* and seem to correct it in some way. It is not always the case; the psychotic patient pays little attention to a communication unless it is on exactly the right wavelength. He is very precise, very exact and does not like interpretations which are off the beam; he usually ignores them as if they haven't been said at all.

Q: If analysis enables the patient to learn to articulate early, forgotten, or put-aside memories, how does that lead to change?

B: It *appears* to be because it is articulated, but I don't think it is true. I would prefer to say that this habit of grunting and making noises is developed by certain animals – the human animal being the most striking example – into articulate speech. It is a recent invention developed over the last few thousand years, which is nothing at all on the scale I am talking about. The important point is not the patient's ability to express something articulately, but that if it has reached the level of the mind where the patient is relatively civilized, there can then be some interchange between this civilized individual, educated and articulate, and a primordial mind. This primordial mind I can pictorialize by taking as a model the fact that it is a survival of parts of our ancestry like the branchial cleft, signs of a kind of fish anatomy, or a vestigial tail.

Q: Is this similar to Jung's archetypes?

B: I think he was probably talking about the same thing. There exists some fundamental mind, something that seems to remain unaltered in us all. If the race develops sufficiently to be able to communicate in terms of articulate speech then it is only rational to assume that that is a total development. But it does not mean, therefore, that there is nothing to it except man's capacity to talk and his consequent ability to give himself the title of '*Homo sapiens*'.

Q: I have been thinking about this process of feelings 'seeping up' into consciousness. It seems it would often happen when the person is having a traumatic experience, like a loss or falling in love.

B: I have described 'emotional turbulence' as a state in which there is this kind of churning going on and all kinds of elements keep on obtruding – as in adolescence for example. (Latency likewise, but it is dealt with in a different way. The person becomes amenable, there are no particular signs of emotional life, because the emotional turbulence is, as it were, turned round; the superficial calm appears instead.) From time to time the individual is aware of this kind of turmoil and aware that there is some development which is striving to take place; the pressure which arises in a particular area is feared as being likely to break out and destroy his accepted method of behaviour. He will then mobilize assistance from other people, trying to get them into the system to help him suppress the forces which are pressing him from inside. The other people in turn then hate the forces which are pressuring them from outside.

Q: When the patient is in this state where he feels that he cannot handle these forces and tries to marshal outside forces to help, obviously one of the first persons he turns to will be you. How do you deal with that? Do you feel you should never handle these forces for him?

B: I try not to influence the patient into a way of life which might conceivably suit me, but would certainly not suit him – that is a negative aspect of it. The more immediate aspect is that I would like to say to him, "You are really expressing" – and then I say whatever I think my interpretation is. The object of that is to introduce the patient to the most important person he is ever likely to have dealings with, namely, himself. It sounds simple; in fact it is extremely difficult. One is always liable to affect the patient with one's own views, both those consciously held and others one is not consciously aware of – the countertransference. The main object is to help the patient to be less frightened of his own horrible self – however horrible he thinks he is. The moral impulse is extremely primitive. You only have to look at a child and say, "Ah!" in a reproving way, and you will see it wince guiltily before it knows any language whatsoever – or so one would think. The moral system, the conscience, cannot be appreciated unless its primitive nature is recognized. Unfortunately we have to use terms like 'superego' which immediately suggests something which is above everything else. It is much more likely to be underneath

everything else, basic, fundamental. It is easy to find various methods of rationalizing it, thus building up a whole rational moral system and a whole mental space for which we have no co-ordinate system as geographers have.

Q: You talk about the fundamental mind which I assume is something like a genetic mind, a mind that comes as part of our accoutrements at birth. When I consider a palaeontologist, someone who may search and search and occasionally find a fossil, and compare it with the process of therapy in which it is difficult to tell rocks from fossils but easy to interpret many rocks as if they were fossils, I wonder how much damage we are doing when day after day with our patients we are hearing phantasies and assuming they represent some part of this genetic mind without really having the accurate tools to be able to tell what comes from the archaic mind and what is simply our own misinterpretation.

B: The disastrous nature of mental interference can only be excluded if it is claimed that psychoanalysis cannot possibly do harm.

We become aware of a mind, or think we do, and build this vast super-structure of theories without any real consideration of what a mind or a personality is. We learn these theories – Freud's, Jung's, Klein's – and try to get them absolutely rigid so as to avoid having to do any more thinking. But we cannot make a conscious and deliberate attempt to help the process of development if we start by being mentally fossilized.

Q: Do you think morals primitive enough to be instincts? And if they are that primitive, what purpose do they serve? Are they for the preservation of the person?

B: The persistence and survival of moral attitudes which may once have been valuable is often injurious. I can see, for example, that patriotism might be a characteristic which is valuable; I think it might be important at some stage of development to learn to be loyal to one's contemporaries. But I think you can get to a stage in which the formulation, possibly valuable at the time, becomes inappropriate if it persists beyond the period during which the formulation and its context matched. The persistence of such a morality can become dangerous. Think of the moral grounds on which people do things today; how easy it is to accuse somebody of upsetting the morals of the nation or the person or group. But we cannot discard these attitudes; the fact that they are primitive doesn't mean that they

are therefore unjustifiable. The analytic investigation should display these qualities so that patients can make up their own minds about them and revise their opinions if they want to – not so that they should go on feeling exactly the same for ever and ever. Even if one has been an animal at some point, it doesn't mean that one should continue to be an animal for ever. Nor, having achieved some sort of civilized status, should one therefore want to stamp out these animal characteristics. Consider genetic inheritance: anatomical and physiological theories seem to be fairly satisfactorily worked out. But are they also applicable to the mind? Does all generation take that same course which has a considerable body of theory attached to it when it comes to anatomy and physiology? Take a primitive form of life like that of the aphid, the green-fly; it is almost a louse and almost a plant. Its method of generation is incredible; it is one of these unbelievable facts. Whole generations are exclusively feminine; they continue to produce through parthenogenesis. At another stage the young have wings, giving rise to another generation which has no wings; and then there is the one solitary individual which is male.

Ought we not to be open-minded about the communication of ideas? It is clear that it cannot be done by one individual – our lives are too short. But the communication of these ideas from generation to generation seems to be important. The method of communication and creation in the mental role is something we have to be prepared to find extremely complex and cannot be regarded as following the principles which seem to apply to physical generation.

We can do nothing whatever about the world in which we live; I can do nothing about the universe of not-me. But I *can* do something about me. In order to do so I have to make a choice – out of a vast mass of facts. But choosing what I am going to pay attention to also involves *not* choosing what I am *not* going to look at or talk about; in other words, inhibition. That process is, it seems to me, indistinguishable from the pathological mechanism of splitting.

Q: When you are listening to a patient, trying to determine what is relevant of what this person is telling you or trying to communicate with you, you suggested a kind of 'free-floating' attention –

B: That is how Freud described it; as good an expression as I know –

Q: – treating it freshly as it comes and also waiting for a pattern to emerge – which to me implies something which slowly builds over

a series of sessions, not one. Is there some way in which you can give us a feeling of how you work, of what you do in an hour or a series of hours? I am trying to get some sense of what it is you are looking for, what it is you do – or is that impossible?

B: I don't think I can do better than I have tried so far, but it does involve realizing that you may learn something about me that I don't want you to know. l have to take that risk. You likewise have to take the risk of finding out something you don't want to know. The position of the analyst is somewhat prejudiced because the patient has already found out that you are a psychiatrist or psychoanalyst and from the outset regards you as an enemy butting into his private life. You cannot, after all, commit a bigger outrage than you do when you enter into, or seem to enter into, a person's mind. In surgery the fact that an outrageous assault is being made on the body is usually accepted, although you cannot rule out the possibility even there of someone taking very strong exception indeed to the surgical interference with their anatomy. A patient consulting a psychiatrist will want to know who this person is who is wanting to talk with him. The psychiatrist must be able to tolerate his extreme vulnerability; the fact that one lives to adulthood means that one must have done all sorts of things which would meet with disapproval if people knew about them – one is vulnerable. In a recent court case it was obvious that one of the attorneys decided it was a good plan to work on the weak spot of one of the psychiatrists. Your patient doesn't know if you are there to gather information which you propose to use against him, or whether you are there to be helpful. It is usually difficult for the patient to believe it is intended to be helpful; it is easier for him to regard it as an outrage on his personality.

Q: It sounds almost as if we have an investment in coming up with an answer which encompasses everything we see so that we don't have to make that assault, so that we can give some distance to the person we are working with.

B: I think that is true; do what we can, we hate being ignorant – it is most unpleasant. So we have an investment in knowing the answer, or we are pressured from within to produce an answer and closure the discussion. Keats, in a letter to his brother, describes what he calls 'Negative Capability'. It is clear that he is talking about this same curious business in which most people want to closure off

what they don't want to see or hear. That makes it difficult, of course, if you also *want* to say what you see and hear. It is one reason why it is such an extraordinary achievement that Shakespeare was able to be so verbal – he could verbally pictorialize things which most people don't want to see.

Q: If we assume that we can be open enough and fresh enough in a session to get some grasp on what is going on, really 'hear' it, and that we can get the patient to believe and to trust the purpose of the invasion is for their long-term benefit, how do we then go about using that?

B: It is supposed that having brought these things out onto the surface you can then forget them, because you cannot forget what you cannot remember. In fact it isn't so simple, because there are really felt to be some disagreeable experiences which are better not remembered. So this question about the therapeutic value of psychoanalytic investigation is far from settled. It doesn't seem, so far, to do any particular harm and there are people who appear to benefit from it. One could argue, philosophically, that it is a good thing for the patient to know who he is if he can bear to find that out, because if he knows who he is then he can have some idea about his capacities and potentialities. In physical medicine it seems to be accepted that it is reasonable to believe that the patient should live even if he is a murderer; not so in psychiatry. I don't think people would agree that it would be a good thing to make somebody into a really efficient blackguard. And yet, why not? If it is all right to mend a person's arm or leg, then why not mend his mind? Of course I could raise a personal objection to it; the first person the patient would be likely to try his skill on would be myself. In war this becomes crystal clear; you may have to deal with a wounded enemy who may start wounding you.

Q: Are you optimistic about what analysis may do to help people submit to this invasion, learning to trust the analyst in order to relieve the pain they find themselves in?

B: No, I am not optimistic about it, although I think that it is on the right lines. I do feel that in spite of the somewhat rudimentary nature of our approaches they are of the utmost importance. But is the growth of our wisdom likely to keep pace with our intelligence? – using 'intelligence' in the pejorative sense of the ability to learn tricks. It is a matter of the greatest possible urgency that the

human animal should discover what sort of animal he is *before* he has blown himself off the earth. The monkey-trick department is far and away in advance of the rest.

Q: For the past couple of years we have been noticing here that when certain employees have upset states these are followed by illnesses – actual physical illnesses – and I have been wondering whether the illness was coming on before the upset state, or whether the body was signalling in the upset state, or was the upset state heralding a major illness?

B: The advantage of the physical illness is that it is almost respectable and it is relatively comprehensible, so that the person who has some kind of mental discomfort can welcome the physical ailment because that at least gets relatively rational attention. There is a pressure in the direction of escaping into what is already known – which may not be much, but it is something. These physical discoveries are made very early. For example, a child can be fascinated by the extraordinary behaviour of its penis which, if it is fingered by himself or nurse or anybody else, gets erect. It's marvellous – it's a part of the body which seems to have a sense of humour, which cooperates and which is friendly. The child has a chance of establishing a friendly or workable relation with its own body which behaves as if it wasn't its own body anyway because it carries on in its own way. There are these peculiar zones of the body which do behave as if they had a brain or mind of their own. If we have to be clever about this and put it into anatomical or physiological terms we would have to say, has the parasympathetic got a brain? Does the thalamus do a parasympathetic sort of thinking? There are situations in which a patient shows great signs of fear; that patient may also have learnt *not* to show them. Such a patient will complain heartily of his blushing. "*Now* I'm blushing"; you look at him and he is as white as a sheet. What sort of blushing is that? *He* knows, because he has been able to mobilize this particular vocabulary. It would be foolish in a case like that simply to dismiss it on the grounds that the patient didn't know what he was talking about, or had got hold of the wrong end of the vocabulary. In fact one has to pay great attention to it. Similarly with a patient who says he is terrified and shows no signs of terror whatsoever; the terror may be so socially unacceptable, and to him too, that he tries to ignore its existence. I find it convenient to think of this as thalamic fear. I could say to the patient, "This blushing you

are talking about is something which is so painful to you that I think you are afraid you might kill yourself rather than have that experience". But is it any good making a verbal approach? – remembering that this capacity to talk is a very late development.

In many of these cases one is invited by the patient to make reassuring noises. But then the patient once more realizes that there is no hope of anybody ever understanding that his blushing is extremely painful, or that the fear is almost unbearable. We must be sufficiently aware of the curious way in which symptoms present themselves, as it were, by their absence, and avoid welcoming the patient who says, "Oh well, there's nothing wrong with me. I'm all right". They invite you to leave them alone; they do not want you to intrude into their personality. Psychiatrists and psychoanalysts are indeed likely to become perceived more and more by the general public as a threat. Their approach to the mind or character or personality is felt to be something which could undermine government itself. People will readily say, "It's all this horrible psychoanalytic nonsense – that's why people are behaving in such an unrestrained manner, sexual promiscuity and all kinds of things – good-bye to all decency". That accusation will become more and more widespread as it becomes more and more obvious that psychiatrists are dealing with something that matters very much.

2

Questioner: I have been wondering why taking a history during an interview is important to me. I don't think I could give that up yet.

Bion: The first thing you have to consider is yourself and your way of working. If it is convenient to you to start off in some particular way you should do so. You can readjust it if you run up against a case in which it seems unsuitable. Patients are often used to this routine of giving a history, and you may as well let them feel at home by allowing them to do exactly that – otherwise it is so strange to them. If you start off by saying, "Now, what do you want?" or "What can I do for you?", the patient may reply, "That's what I came here to find out", and will not move from that point. You are straight away in the middle of a story without knowing anything of its beginning. The essential thing is to give patients as much help in that way as you can, because they are the people who don't know what they are up to. If it can ease the situation for them to follow the sort of routine they are used to that's a good idea.

Q: I would like to get a concrete idea of how you personally work with patients, to what extent you guide the direction of a patient's introspection and talk as opposed to letting the patient talk about what he or she wishes.

B: I would like to be able to say that I don't guide them, but in fact that is not true. It is a great mistake for an analyst to imagine that he doesn't. Theoretically you leave patients plenty of space to say whatever they like, but in fact your mere presence distorts the whole picture. They take one look at you and make up their minds either that they are prepared to talk to you, or that under no circumstances will they do so. The relationship between the two people is a two-way affair and in so far as one is concerned with demonstrating that

relationship it is not a matter of talking about analyst and analysand; it is talking about something *between* the two of them.

Q: Most people talk about personality or mind as if it were located *in* a person. It seems to me that the only sensible way to think about personality is to talk about a functional relationship.

B: What I have just been saying about the patient applies also to the analyst; the physical presence of somebody else in the room dominates his ideas. You can see the person; you can hear the person; therefore you are powerfully stimulated by your senses. We believe there is a character or personality which has the same sort of boundaries as the physical body which can be seen and heard. Why does one suppose that there is some kind of mental phenomenon? If you watch any group of people – a crowd at a football match for example – you get the impression that there is more to it than just the physical presence of those people; there is some sort of communication that is not visible. It is audible because of the cheers or shouting – there is a verbal expression. But it is a verbal expression by something which is not sensuously perceivable.

Q: Although I have entertained ideas of the sort you are mentioning, I find myself afraid in the therapy session to act as if they were true. I think my fear is that I would be behaving much more crazily than the patient ever could.

B: I think you are right. If one assumes that there is a mind, then the question arises, what sort of mind? Terms like 'crazy' are widely used – one wonders why. Can there be this widely accepted word unless it is about something? And if it is about human beings, as it always is, it is difficult to imagine that one is somehow exempted from exactly that same situation. So I think it is only right to assume that if it is fair to talk about people being crazy or sensible, then it must be true of all human beings. It would be foolish to imagine that one is ex officio sane or sensible and that other people are not.

Q: I am not sure that I see how that follows. Certainly the word 'blonde' applies to human beings, and yet some human beings are blonde and some are not. I may agree with the conclusion, but I am not sure that I know how you are getting there from the notion that since the word 'crazy' applies to human beings, then it must apply to all human beings.

B: Because it is so universally applied, such a common-place, one of these words which are used over and over again. I don't know

enough about foreign languages to know how widely spread it is; certainly there are some words which have a universal currency. But I don't think linguistics would get us very far – we, as analysts, have gone beyond that point already.

Q: How does this and the things we have been talking about relate to what you actually do behaviourally in working with somebody who is your client?

B: That question is a difficult one which has, in a way, been vitiated already because there are such masses of ideas about what we do. In fact when you and the patient are seated in a room together, that is a unique situation – if we are right in supposing that we need to respect the peculiarity, the speciality of a particular relationship. An individual comes to see me, he thinks I am a psychoanalyst; I think he is a patient. In fact I don't know. What would you do? Would you talk, pass the time of day? Closeted in a room, alone with a strange person, you have to decide in a flash how you will behave. When the patient comes into the room you have to make up your mind there and then, with very little information to go upon, what you will do. At that point I think one is justified in falling back on theories. In physical medicine you are supposed to be able to observe the difference between a patient who has a cachectic flush and one who has ordinary sunburn. A good physician will walk into a ward and will notice that somebody is extremely ill, or somebody is showing other signs which obtrude themselves on his perception. In analysis the same thing applies; we are supposed to be able to notice some quality which makes us think that one particular person isn't another particular person. For about three sessions the whole of psychoanalysis is very useful – that is all you have to fall back on anyway since you know nothing else. But it is only useful because it might enable you to say something appropriate to the person concerned, passing the time until you know who you are talking to.

Q: I am curious to know what you regard as generally appropriate behaviour for a therapist.

B: My reaction to that is that you cannot say what is appropriate and what is not. Fundamentally there is nothing that you can do about it – if you can, then it is wrong. What patients have to realize is that they have to put up with having me there. It is useless my wanting to give the impression that they are dealing with a doctor or analyst; I have to dare to be alone in the room with someone who

can have his own opinion about who I am. This may not be at all the sort of opinion I would like, so it is a matter of not minding that situation. One of the advantages of having an analysis is that you get used to the fact that your analyst makes comments about who you are, so that by the time you yourself are treating people you may be more able to tolerate that situation.

Q: Patients will often verbalize that they want to know who you are or know something about you. I had a patient last week who was very keen that I call her by her first name, very upset that I would not. She had just seen another therapist who had been recommended to her and she was quick to point out that he had called her by her first name. She asked why I didn't. She felt estranged from me – if I cared about her I would call her by her first name. She said, "The only people who call me by my last name are bill collectors". How do you deal with that?

B: It is difficult to say because I wasn't there. I might have said to the patient, "I think you must be very afraid of what I would call you if I were honest. You are anxious that I should diagnose you as Mary Smith or whatever. You don't mind if I call you by a particular name of your choice, but you are afraid of what the words would be that I would use if I were honest". But I don't know the patient nor whether she could stand that.

Q: She could stand it. She feels she is a whore; this is what her father has implied. She says, "Because I have sexual desires for more than one man, my father must be right". She is having an affair with another man; she is married and has children. In some ways she wants to be closer to me at this particular point. She wouldn't be put off by what you suggest; she would get irritated with your reply and insist that you call her by her first name.

B: Why not the second one? Why not whore? Or prostitute? If she isn't one, then what's the trouble? Is she wanting to be called a prostitute or a whore? If not, what is the point of the story? What convinced her that her father was right?

Q: She wants sex with other men besides her husband, therefore in her view she must be a whore. She's afraid that if she got a divorce from her husband she would run around and have sex with all sorts of men – behave like a free whore.

B: In view of what you are saying I think I would try to draw her attention to the way in which she wishes to limit my freedom about

what I call her. It is just as much a limitation if the patient wants you to give the correct interpretation. Why shouldn't I be free to form my own opinion that she's a whore or that she is something quite different? Why be angry with me because in fact I am free to come to my own conclusions?

Q: Her fear is that your own conclusion will be that she is a whore.

B: But why shouldn't I be allowed to come to that conclusion?

Q: So you conclude she is a whore – now where are you?

B: But I haven't said that I do. The point I want to show is that there is a wish to limit my freedom of thought. To exaggerate it for the sake of clarity. It is ridiculous for a patient to come to see a doctor and say, "Doctor, I've got a lump in my breast. Now, I don't want to hear anything about cancer or anything of that kind". Is the patient coming for a diagnosis? If not, what is she coming for? It is not fundamentally different if the patient wants to lay down the law beforehand about what you are to think or feel about her.

Q: I gather there are basically two trains in your thinking. One is that you are primarily interested in interaction between you and the person in the room – not too interested in what takes place outside the room. The second is that you are primarily interested in noticing patterns of this person's behaviour; you seem to be asking not *why* the person is this way, but *what* and *how.*

B: Although I would like to have knowledge, from whatever source, about the person, my justification for sticking to what I can see and hear for myself is that experience – which is not simply experience of psychoanalysis – has persuaded me that hearsay evidence is extremely unreliable. It is frightening to feel one is limited to what one can observe for oneself, because you learn the fallibility of your own senses. But at least if you can see and hear for yourself you can have a certain amount of evidence for what you are saying.

Q: Would you discount, therefore, the fact that the girl's father called her a whore? Would you try to find out if she were a whore, or if she thought of herself as a whore?

B: No. I think I would feel that it told me more about the father than about the daughter. This is one of the snags about an interpretation. A patient may not know much about me or psychoanalysis, but my interpretation will tell him more about who I am than about who he is. I hope it will tell him something about who he is, but even if he

feels that what I say is right the fact that I say so tells him something about me.

Q: What is the advantage of that?

B: There seems to me to be a great deal of value in respecting the facts. Therefore patients need to have some respect for what they see the facts to be.

Q: You've got me puzzled. I can readily see this in terms of some of the research into psychoanalysis and psychotherapy, saying that the patient adopts a relationship with the therapist and in a sense imitates or incorporates aspects of the therapist's personality. But I don't see the facts, because the impression I am getting from you is that interpretation in conversation is basically to keep the meetings going so that something like black magic takes place and the patient changes his behaviour based on the incorporation of the strong ego or good ego of the therapist. We do know that some therapists live rather wild lives and their patients end up having wild lives. Some therapists are rather conventional and their patients end up being rather conventional. So I wonder if it is the facts, or just a technique by which you can keep the relationship going until something magic takes place.

B: Here again I shall have to fall back on theory which is a sort of summary of my experience. The human being is what I would call extremely *clever.* There are certain animals which are clever – circus trained animals, for example, can behave exactly like a Lord Mayor's procession. So you can be certain that the patient will be able to behave exactly like the analyst – and that is indeed what they learn to do. The patient only has to go on coming for a certain length of time to have a pretty good idea of the analyst's various foibles and habits. That patient can be *just like* the analyst and be cured *just like* the analyst. The trouble is that it doesn't seem to be adequate or satisfactory. It is the result most easily and quickly achieved; getting to a stage where the patient does not become just like the analyst, but becomes someone who is *becoming* somebody, is more difficult and somewhat frightening – it might mean becoming insane. Patients will, therefore, often prefer to fall back on being like the analyst. We can see how children quickly pick up the bad habits of the parents. The bad habits of the analyst will be reflected in his patients every time – very fast.

Q: Could you give us examples of the kind of bad habits you exhibit?

B: No, but my patients could. I can only hope that these characteristics will help rather than hinder the patient, that I am the sort of analyst who is less of a liability than an asset.

Q: When you are talking I have a sense that you are saying what doesn't happen rather than what does. For instance, you can't say specifically what the bad habits are because you are not aware of them; or when you give an interpretation it is more a reflection of the therapist and who he is rather than of the patient; or you talk about diagnosis of the patient in terms of what you are not looking at, or what you are not doing.

B: What I *am* looking at is what lies beyond the sensuously perceptible. Therefore you are quite right in saying I am talking about what sensuously *is not*.

Q: I notice in your conversations that rarely do you ask 'Why?' You ask 'What?' or 'How?' of the patient, and that reminds me of the kinds of basic patterns of human behaviour that Piaget or Lévi-Strauss work for. I wonder if you are moving the same way.

B: Certainly; it is a basic, underlying pattern. One could go on interpreting ad infinitum matters which are of very little consequence or importance, but one would really like to interpret the fundamental thing, the fundamental language. In physical medicine this would be clear; you are not concerned only with what obviously presents itself for inspection. What you want to know is what lies behind that. Why is this patient not simply pale? Why do I think that this is a peculiar kind of flush? That is difficult enough in physical medicine; in the kind of thing we are talking about it seems to me to be infinitely worse. That is why I think it would be a good thing if we could consider in the course of ordinary life, ordinary experience, what this fundamental language is.

Q: Would you suggest a direct intervention to get at that level?

B: No, because owing to the cleverness of the individual he can always counter that; he can feel "I don't want to hear there is anything wrong with me", and instantaneously responds by a defensive barrier so that the screen is drawn over again.

Q: How do you deal with it?

B: I don't know.

Q: But you do it, I know.

B: I think that one does sometimes. People do hope that the doctor will not be taken in and will find out what is the matter with them.

I don't think people come to us because they have been told to – that may be a rational explanation of their rational behaviour. They themselves might be hard put to it to say why they come. Indeed one of the difficulties we have to deal with is a morality which has been forgotten and which we were probably never aware of anyhow. That is why, when a patient comes to see you, it is so difficult to know what sort of idea to have in mind. Rather than consider the situation as spaced in time – past, present and future – you would have to consider it more in terms of a military map in which it is all portrayed on a flat surface, linked up with various contours. This means that talking to a person it is all 'now', 'here and now.' Can you distinguish one part from another? And if so how would you do that? One way is to say to the patient, "This has a very long history; these are feelings you had even as an infant before you could actually verbalize them". I am doubtful about that method; the patient *may* be able to understand what I mean by that and to observe the characteristic to which I am trying to draw attention. But I don't know what sort of language is to be used. In the *Phaedo* Plato reports Socrates as talking about the ambiguity of verbal communication. He points out that the spoken word doesn't tell you anything more than a painted picture; it is as ambiguous because a painted picture has to be interpreted. In the space of two thousand years I don't see that any progress has been made with this problem. Occasionally a philosopher, like Kant, observes once again the ambiguity of language and the need that it should be made more precise and more exact. I am sorry to say that it seems to me that we, as psychiatrists and psychoanalysts, often behave as if it weren't a problem, as if we can do something with the language we talk even before having tidied it up.

Q: I think you are asking too much of man.

B: It is possible, but the fact that *I* ask it doesn't matter in the least.

Q: Suddenly, as you were talking, I remembered a story. I once worked with a man, and in the course of our conversation I said, "The thing you should not do is go to college"; I gave him all the reasons – and he left. Two years later I was driving in a remote town in Arizona and stopped for a cup of coffee. Suddenly this same man came in, shook me by the hand and said, "Thank you very much for talking to me". "What did I say that helped you?" I asked. "You told me to go to college". People don't listen. The role of the therapist is,

in a sense, to be there, something like a blackboard. Maybe that is your key – maybe you are so busy puzzling out what the patterns of this person are that he has the chance to reflect upon things in your presence.

B: A lot depends on whether the patient can turn the experience to good account; I would like if possible to make it more likely that he could turn it to good account than bad. What matters is whether the person can have enough respect for the reality, for facts, to allow himself to observe them. I once worked with two surgeons, one of whom had a world-wide reputation, Wilfred Trotter, and the other who was locally well known and extremely proficient. If Trotter did a skin graft it took; if the other one did a skin graft, perfect in technical equipment, it sloughed off and was rejected. Wilfred Trotter, who wrote *The Instincts of the Herd in Peace and War*, always listened with intense respect to what the patient had to say; he never brushed patients aside as unimportant. He never even brushed them aside because they were so important. I saw him when he was called in to deal with royalty. He simply sat down on the bed and proceeded to listen to what the royal patient had to say. He said, "Right, we'll fix it". He then carried out what ought to have been done long before – a perfectly orthodox, simple rib resection. Nobody had ever been able to treat the royal ribs so disrespectfully before.

Q: I wonder if you are so busy trying to understand and listen to the patient that your comments are really designed to encourage the patient to keep talking so that you can observe him more.

B: Perhaps, but if you are lucky the patient may also feel that he could likewise dare to pay attention to such facts as exist – however unpleasant. That is the difficulty – facts don't make themselves acceptable to the human being. For all the laws of science there isn't any evidence that anybody or anything obeys those laws. It would be convenient if the world of reality kept within the bounds of our comprehension – but it doesn't and there is no reason why it should. That is why it is so important that we should have some respect for the facts; then somebody else might similarly dare to respect the facts again – it spreads.

Q: There is some controversy in psychoanalytic circles about the value of seeing the spouse or members of the family of a patient. With your concern for the facts and avoiding hearsay, I wonder if you could comment on that.

B: I have found that in certain situations I have been unable to avoid seeing the family. I prefer not, because I find that the amount I get, even from an apparently uncommunicative patient, is so vast that it is as much as I can cope with. If it suits you to see the entire family, then that in my opinion is what you should do. It is no good resorting to the method which suits somebody else. The fact that other people do differently is useful – it may give you a hint – but the fundamental point is, can you find out what suits you?

Q: You have talked about goals which you have in therapy, one of which is presenting patients with facts about them as you see them, the truth about themselves; the other is being available to them as a person. I am troubled about whether these are compatible.

B: Making yourself available is something which is more easily understood if you simply regard it as any other commercial advertisement. You must make it known that you exist, that you have a name and address. Who you are, what sort of person you are, is a matter of opinion which the analysand is free to form for himself. The analysand may be able to deduce who he is from the mirror which is presented to him – preferably without too much distortion – by the analyst's attempt to reflect back the meaning of his free associations. The analyst does not in fact tell the patient who he is, but leaves him to form his own opinion from the mirror which the analyst has tried to hold in front of him. It is a mistake to think that the analyst can tell the patient what his own character is; any such attempt would only be a distortion of the mirror. I do not think the fact of the analyst's personality is incompatible with the attempt to speak truly.

Q: You have talked about how, when you are with people, you are bombarded with a lot of information which is ambiguous and that what you are seeking is to find facts and truth. What do you mean by 'facts'?

B: I mean that I believe there is a fundamental reality even if I don't know what it is; that is what I would call a 'fact'. But we are prisoners of our senses. *"La réponse est le malheur de la question"* [Maurice Blanchot] – the answer is the misfortune or disease of curiosity: it kills it. There is always a craving to slap in an answer so as to prevent any spread of the flood through the gap which exists. Experience brings it home to you that you can give what we call 'answers' but they are really space stoppers. It is a way of putting an end to curiosity – especially if you can succeed in believing the answer is *the*

answer. Otherwise you widen the breach, this nasty hole where one hasn't any knowledge at all. In certain physical situations there are ways in which the hole can be blocked in a more or less convincing manner; if you are aware that you are hungry you can put food into your mouth and hope that will, as it were, shut you up; a mother can stuff her breast into the baby's mouth – if she does it with feelings of anger and hostility that is a different state of affairs from doing it with love or affection. Even in the domain of mental curiosity, of wanting to know something about the universe in which we live, that hole can be blocked by premature and precocious answers.

Q: Can the analyst guide the patient by expanding the space for curiosity when that seems to be the path for the patient, and by giving an interpretation or answer – not an omnipotent answer but one that might limit the space?

B: One would like it to be something like that. I am very doubtful that it is so because we cannot help sharing the itch of the patient to fill the gap. He wants to believe, and is likely to seize on any excuse to feel, that the analyst does know. And of course the analyst is quite happy to oblige. It is difficult to resist that; if you do you can equally choke off all curiosity – people think you are deliberately withholding information or knowledge.

Q: At Tavistock conferences they often say that 'the answer lies within the group'. They use this phrase over and over again. Upon examination it sounds at first as if it is definitive, that it means there is an answer and it is right here among us. And then upon closer examination it is infuriating because the search, this endless search around the group for the answer usually does not turn up an answer. I wonder if you would share a few thoughts on that theory – 'the answer lies in the group'.

B: I think it is a convenient idea because it restricts the area of search. If you were lucky there would be truth in it. The problem is, does the answer kill curiosity, or is it a prelude to an informed and disciplined curiosity? Any statement is valid as far as I am concerned if it is a prelude to the exercise of disciplined curiosity.

Q: Do you believe that a group has an unconscious?

B: I wouldn't want to abandon that idea; nor would I want it to obscure the discovery of what else the group has. It is easily done. I could say, since I have a body why not leave it at that? Why confuse the whole thing by supposing that I have a mind as well? We all know

that the theory of conscious and unconscious has been quite productive; it may have been sufficiently productive to make us doubt its efficacy or use now. If you make a group approach, then it may become clear that this will have to be augmented with some further theory, because the existing one, valuable as it is, is nevertheless not good enough for that purpose. For some time now the law courts have been talking about 'rehabilitation'; they even call on people like us to express opinions, because they are aware that those time-honoured and experienced forms of treatment – guilty or not guilty, punishment or let them go free – are no longer good enough. So an open-ended curiosity is revealed; it is ever-expanding; the whole way of conducting our affairs is called in question.

Q: I am having problems putting together some words like 'clever', 'wise', 'intelligent'. You seem to me to say that we should have the common sense to listen to a basic language – that is my own interpretation.

B: Of course, in order to have common sense you have to have senses which work in common and that would seem to be fairly successful because it seems to happen anyway; the infant is able to co-ordinate what it hears and smells and sees. It is difficult to say how one achieves a certain common sense; it is easier to see that as we grow older our senses tend *not* to work in common. I was once an athlete; I couldn't be an athlete today because my physical functions aren't sufficiently coordinated. Presumably this applies also to one's common sense.

Q: So everything is on-going and constantly changing?

B: I think so. This is why I have talked about 'turbulence', I take the example of Leonardo's obsession with drawing water and hair. He could in that way skilfully 'draw a line' round that idea or feeling. In our work this turbulence sometimes becomes sufficiently obtrusive to be given a name; adolescence, for example. Does that answer anything? Is that one of these space stoppers, so that you never enquire what has happened to that turbulence, why it is emerging just then, why it is that when you think you are talking to your little girl she turns out to be a young woman *while* you are talking to her; why, when you think you are talking to this irresponsible little boy, he is in fact already a young father.

3

Questioner: Do you still do group work, or are you still interested in group work?

Bion: I am still interested in it, but I get very little chance to do it because I get so much pressure on me for individual analysis which I find extremely rewarding and interesting. Is anybody here taking groups?

Q: Yes; but I doubt the use of applying group relations methods to patient work. I don't think it works very well from what I can see of running a small group of hospitalized people.

B: You don't find it helpful with the actual family group?

Q: I don't feel ready to use it with families yet. I do get a sense of sub-groups forming and of groups getting into basic assumptions – I think family life is an established basic assumption, the pairing group in a sense. At present I find it difficult to deal with the complexity of the inner actions in my own life.

B: One thing which strikes me in dealing with the individual is how little consideration seems to be given to this question of what is basic, what is fundamental. Is there any way in physical medicine of defining what the fundamentals are? What does the doctor concern himself with? What could you call fundamental in the sense of wishing not to diffuse your observation or your time?

Q: I have often wished that in psychiatry there was something as fundamental as the vital signs – blood pressure, pulse. One can consider vital signs in psychosomatic medicine, and in psychiatry too I suppose, but it is much harder in working with groups or individuals in therapy to have something as a baseline of 'normality' as readily as the blood pressure, pulse, respiratory rate and temperature. I am

not sure if that is what you are talking about when you say 'fundamentals'.

B: I think it is.

Q: Even more fundamental than that I suppose is that when in physical medicine a person presents himself to a physician and says, "It hurts here", if you look there you may find something in that vicinity and the patient is able to cooperate, to participate in helping you to identify at least some parameters, some areas where you might look for what hurts. But in the mental arena you may look in one place while the trouble is somewhere else. Most of the places the patient points to are cover-ups – it is more respectable to point to the area in physical medicine.

B: We should not overestimate the importance of pain. Even in physical medicine some pains are extremely acute but not particularly important. Some parts of the body are extremely sensitive to pain, so if the intensity of pain were the only criterion one would be led astray.

Q: The intensity of the pain, or the area of the pain gets the attention of the helper; the patient, therefore, participates more.

B: I agree. I am sure that it is important that one should regard pain as being a most informative symptom, but the intensity is often minimized or otherwise disguised. A patient says, "terrified"; the analyst must distinguish a fundamental even when covered up by a cliché. Even in physical medicine of course one has to diagnose, 'interpret' that pain.

Q: I think we in the field of psychiatry have done more to try to interpret that pain. Our language has more descriptive terms developed for that.

B: Yes, but still shockingly inadequate. It is extraordinary, from our point of view, how little progress has been made in that respect – especially since we attach so much importance to verbal communication. It is difficult to know what is the fundamental function of language. Is it to communicate helpfully in the way a mother would want to communicate with her child? Or is it in the service of deception and lying and evasion? Deception and revelation are both fundamental activities. Taking your experience with children, what is your impression? How soon does the verbal communication become of importance to the child? And why?

Q: There is a variance in the time when children begin to develop language – possibly across socio-cultural levels. It would be important to know what is the social field. What are the acceptable sounds at a certain point? What are the social consequences of making a particular sound at a particular point? And what particular sounds does one make?

B: I am impressed by the fact that the physical birth is so impressive. The obstetrician's view, the gynaecologist's view, the statistician's view are all based on "When were you born? Date? Time?" The *fact* of birth certainly impresses the individual and the group. But it seems to me that it is too limiting to assume that physical birth is as impressive as many people suppose it is. In physical medicine it is recognized that the prenatal history is of great importance.

Q: Do you feel this is important in clinical work with patients?

B: I think the lack of discussion of this point is a blind spot. Freud developed this idea of 'the impressive caesura of birth', of our being too impressed by it. He didn't investigate it deeply – a great mistake from our point of view.

Q: In what way? How would you utilize it facing your patient on the couch? How do you use the trauma of his birth?

B: The first thing to do is to be aware of its existence. If there can be vestiges of what a surgeon would call 'branchial clefts'; if, in our development, we do indeed go through these peculiar stages of fishy ancestry, amphibian ancestry and so on, and it shows signs in our bodies, then why not in our minds? This is a purely academic thing we can talk about here; but what do we talk about, or think about, or observe when dealing with a grown man who comes to you with some complaint or another?

Q: Or a five year old child –

B: All right. Do you consider that the child is born on its birthday? Has the full-term foetus no character or personality?

Q: We had the very special experience of having a premature baby. I had a relationship with that child – born five weeks early – during the three days in the labour room before his delivery. I felt I knew his personality. The doctors kept coming in to take the foetal heart-beat to determine whether or not they were going to let him arrive naturally. He had a very strong heart-beat, although they were afraid they were going to have to do a Caesarean section. But they didn't have to and I felt the strength of that child.

B: In a sense it would be possible wouldn't it, that the demands of physical medicine made it impossible to wait until the child was mentally ready to be born? One could say the time of birth was dictated by some critical situation which was not in accordance with what one would suppose was the natural development of the child.

Q: It was clear when he first arrived that he was not fully prepared. Compared with the second child, who was full term, his instincts weren't fully developed. He didn't nurse as well; it took a lot of coaxing before he was able to feed himself, to take the breast. Whereas the other one instinctively did. He had an immature liver so he was jaundiced and sick.

As you were talking I was thinking – I never put these things together before – that he was forced to be doing things mentally that he wasn't ready to do by facing the world five or six weeks early. That has been a characteristic of his behaviour ever since. He is mentally precocious now and always seems to be trying to do things several years ahead; his best friend is about five years older than he. I don't know if you can make a connection – I never thought of that connection before.

B: We don't know. The point about discussing it like this is that we can mobilize the experience of everybody here and then perhaps be open to some sort of behaviour pattern which would be more understandable if one took into consideration the points you have been mentioning. I find it useful for myself to make a distinction between intelligence and wisdom.

Q: When you talk about the pre-natal period what are you thinking of?

B: I am thinking of it strictly in this sense of the period before physical birth, accepting the caesura as being of as much importance as it appears to be – simply for purposes of discussion. But whether it is as important as it appears to be from the physiological standpoint when it comes to the mind, is another story altogether. We have to use physical terms for this subject, borrow from physical language. I now feel – and I think that it seems to me to be borne out by experience I have had and am still having – that there is a lot to be said for considering that we are observing a symptom which will not be understood if it is supposed that it only develops *after* the child's birth. I wish it were possible to discuss these matters without having to invent a language as if it were scientifically accurate. But it is the best we can

do until such time as it becomes possible to use it scientifically. It is useful to consider 'sub-thalamic' fear, meaning by that any of these emotions which have not risen to the point where they could be called 'conceptualized', or conscious, or verbalizable. Take, for example, the premature infant you were speaking about. What sort of mental life can you observe in that person? – assuming that you are dealing not with a premature baby, not a physiological object, but a premature mind. Or consider the auditory pits, or the optic pits. Embryologists have their views about what these extraordinary objects are, because experience shows that they appear ultimately to turn into ears and eyes. If pressure on the eyeball can make you think you can see light, then isn't it possible that pressure could create some similar effect on the foetus when it is living in a watery environment? When, from that point of view, is it able to 'see' or 'hear'?

Q: It has been found that the foetus can hear and responds to musical sounds.

B: Not the slightest doubt about it –

Q: The foetus moves *in utero* in response to certain tempos and responds to finger pressure.

B: I wonder when the psychiatrists and psychoanalysts will catch up with the foetus. When will *they* be able to hear or see these things? A very young child has no difficulty in observing, but its observations may be regarded as having less validity than the possibly less sensitive ones of the adult who may respond, "Yes – come along, don't waste time like that". The child obediently accepts the low estimate made of what it has sensed; it is suppressed and comes back as "the return of the repressed" [Freud, 1915d, page 154]. It doesn't come back into notice unless it becomes sufficiently dramatic; the grown person behaves in a way which seeps through to conceptual thinking and at last someone says, "This person is hallucinated, deluded". But that may be the survival of some kind of capacity for seeing and hearing things which the adult regards as insane or neurotic.

Q: How would you tie this in to your thinking or experience when actually working with a patient?

B: If possible you have to be open to impressions. Unfortunately the whole of our training seems to be at the sacrifice of our animal characteristics or our animal ability. I had a patient who didn't seem to pay the slightest attention to what I said, but was fascinated seeing my words going over him, and then thinking he saw them caught on

the pattern of the curtains. I have also seen a very young child most amused at a frieze round the top of the wall of his room because those colours had a meaning which was comprehensible enough to make him laugh. The fully developed and possibly intelligent adult who sees jokes which we cannot is called 'crazy', or 'insane', or 'psychotic'. Are we right, or is this simply a lack of observation, a lack of being sensitive to the facts? Is it because one does not and cannot see what the patient can see – like those sounds going through the air and getting stuck on the curtains?

Q: Did the patient say he saw that, or was that your inference from the way he behaved?

B: That was my inference from the way that he behaved.

Q: What did you see or hear that enabled you to infer that?

B: I could see him watching in that sort of way; I could also observe that he had not the slightest idea of what I had said to him. He attached no importance to the ordinary – from my point of view – way of thinking or talking. The pattern of the sounds that I made was not of any consequence to him.

Q: Does something have to have meaning in order to give someone delight? For instance, the colours around the room which delighted the child.

B: I don't see why it should have meaning for anybody; meaning depends upon our interpreting these observed facts. In physical medicine you can say, "Yes, the patient has a cachectic flush. That means . . .", and then you launch off on your diagnosis. All that depends on interpreting the facts which are obvious to you, but first of all the facts have to be obvious. That is why clinical observation is so important. A precocious child can see and observe *and* attribute a meaning to what is seen and observed. What about a precocious foetus? Could that be said to attribute a meaning to what it hears and sees? If so, suppose the foetus could hear angry sounds. Would it be able to interpret them? Would it be able to attribute a meaning to them? And when you see that patient at twenty, thirty, forty, whatever age, are there certain meanings which that patient attributes to what is going on which would make you think that meaning would be comprehensible if I were talking to a foetus? The only reason it isn't comprehensible is because I am talking to an adult.

Q: Thinking in terms of what this would imply or mean when I am seeing patients from my clinical practice, it is hard for me to

assimilate what kinds of things you attend to as facts, and what you use for making interpretations.

B: It is very difficult to explain, partly because the language we have to talk is so ambiguous. If I were demonstrating a patient's physical condition I could say, "Look, that colouration of the skin there – it isn't just a bruise; it is something else, a symptom or sign of some underlying and more important – from a medical point of view – fact". By discussing it here we may be able to become a bit more sensitive to what we see the moment we get into contact with actual patients. It requires a training which enables the physician, surgeon, psychiatrist, to denude himself of his preconceptions and be vulnerable to the facts. Knowing a great deal of medicine may be quite useful – one assumes that it is – but what is much more important is that it should not be at the expense of one's senses. When we see or hear a patient we should at once be sensitive to what we see and hear, and from that point of 'observation' go on to the 'meaning'.

Q: You mentioned earlier the word 'reason'. Since the seventeenth century, when Hobson and Locke were much concerned with reason, most philosophers have agreed that there isn't such a thing; that what is reasonable to us may not be reasonable to someone in China or an aborigine. You said that to learn is to be completely open to the 'reason' or the modes of operation of human beings whatever their backgrounds may be. What kind of an approach, if there is such a thing besides a complete openness, can we as a group rely on to communicate? You stress the limitations of verbal communication, but there must be some basics that can transcend national origin, language and so forth, beyond just being completely receptive to the spoken word.

B: It is difficult to say. It is brought home to all of us who have children whom we hope to educate. What are we to do? About the only thing that seems to be basic is not so much what we are to *do,* but what we are to *be.* That is why it is so important if the parents are capable of what I call passionate love. Then the child has a chance of learning something from the way the parents behave. Nothing in their school education or anywhere else can teach them this.

Q: I can see there is no cut and dried method of communicating, but I feel that the mother's love for the child, the nurturing love, the warmth, a hug or a kiss that is meant sincerely, is something that any

human being could understand and feel. If a family were to give this to a child they would obviously have a far better chance than someone who didn't receive this kind of warmth.

B: It might perhaps help to explain something I mentioned earlier – the two superbly trained surgeons, one of whom had *become* something and the other who was just *like* a surgeon, but could never become one – not in this fundamental sense. It is most mysterious.

Q: This same phenomenon has been observed in different teachers. One can use all the media and follow all of the rules and do everything to perfection, but the children don't learn; another, by some mystery of being in the classroom with the students, succeeds in getting them to learn. I suppose it has something to do with relationship – caring about people and transmitting it in some language no one knows about yet.

B: In a crude way we can say one of them is ill and the other is not. But in fact we are dealing with something which is not pathological, something which requires a great sharpening of the senses and perceptions. Can we in any way find a method of excluding what is irrelevant and concentrating on what is fundamental?

Q: It seems as if that is really the dilemma that is being raised in these discussions. If I understand what you have been saying, you are pointing out that when we start out in the world, whether one looks at the point of birth or something prior to that as being the onset of mentation, we begin a process of responding in some cases with a great deal of painful sub-thalamic emotion to the chaos of all that there is to know and experience and feel about being alive; and then we immediately begin this process of attempting to categorize, to know, to find meaning – presumably to prevent some of the pain and maximize some of the comfort; and that in this process of categorization you have to start excluding; and once you start excluding then you begin to lose the ability to perceive everything.

B: Yes – it's the dilemma of choice. You cannot be a responsible person who makes a choice without inhibiting what you don't choose to observe. You can carry this to a point where inhibition begins to slide into the spectrum of a pathological condition, inhibiting one's capacity to see or hear.

Q: Hysterical blindness would be an extreme example.

B: Yes; by that time it has become sufficiently noticeable, so to speak, to be given a label of its own.

Q: The psychotherapist hasn't quite reached that point yet!

B: Not yet, but later perhaps people will say, "Well, all these hysterics take up psychoanalysis". In a way that seems to me to be possible. Curiosity is so often linked with danger. The animal seems to smell out a danger because that is what it needs to know; that is one of the most primitive, long-range senses. For the human being it is very short-range. We can say a noise is getting too great or intolerable; there must be a similar way of sensing that a smell is too strong.

Q: The example you just mentioned brought something to my mind. In a combat situation we had Cambodian and Vietnamese scouts who could smell the nearness of the adversary and see signs which the Americans were incapable of seeing. But after two or three months the Americans were able to see and smell more because they had to train their senses for survival.

B: In certain intimate situations one would like to be able to communicate that – particularly of course to one's children. If only we could enable them to smell a danger or develop some sense which makes it possible to detect danger at long range.

Q: When you were talking about the patient who watched your words being caught on the curtain, I was wondering how you tested your hypothesis to find out if it was valid. What did you do with the information? How did you communicate with him?

B: First of all, it took me a long time to observe that fact. Indeed, this is one of the complaints made by patients – "I come to you for analysis; nothing ever happens; I am just as bad as ever I was" – and unfortunately it is true that it takes a very long time before a point of this kind emerges. When it emerges sufficiently for me to be able to verbalize it I also have to consider whether it would be possible for the patient to verbalize it. He may ignore my interpretation either because it is wrong and just passes him by, or because it is correct and he doesn't like it. He can feel, "This analyst is crazy" – a situation where the patient instantaneously projects his own feelings or fears of himself onto the analyst. Sooner or later we have to decide whether to give that interpretation or not. I gave the interpretation; the patient agreed with it and said he thought I would never be able to see the obvious – in fact he blamed me for taking such a terribly long time to say something which was so clear and so simple. On the whole that seemed to bear out that I was correct, rather more than it would

do if the patient said, "Yes" in complete agreement, but meaning nothing whatever; you know the patient is agreeing because that is the kind of thing he thinks you want him to do. These are matters of information. It is difficult to say why one 'yes' seems to be of greater significance than another – the fundamental ambiguity of language again. It is only a kind of elaboration of the grunts and noises made by an animal; we have learnt to be somewhat more expert in the use of our musculature.

Q: Could the patient make use of it in the sense of beginning to hear you more, beginning to assimilate some of the things you said?

B: There was a marked change in his behaviour after that. I can't remember now what it was, but at the time it convinced me that he was right, he had been saying this for a long time without any adequate response from me. When I did respond he was able to transform what I said in a way which made it possible for it to seep from conscious rational levels to other levels of mind.

Q: Isn't it because we not only make a sound to verbalize the interpretation, but it carries with it intonations, posturings that set up reactions and expectations such that the patient can now have this experience – which he would hitherto not have dared tell anybody in the world because no one would believe him – knowing that now someone believes him and that he is not going to be harmed for having the experience?

B: One assumes it must be something like that; the patient can become so used to having some statement of his dismissed as 'an hallucination', 'a delusion', that it is clear to him that the doctor regards him as crazy; he will not therefore make those communications.

Q: If the patient knows what he is doing and you know why he is doing it, why interpret what he is doing other than asking him why he is doing it?

B: This is another mystery. Why not pass it over directly from himself to himself? Why is an external person necessary? Why can't the human being be like *lumbricus*? Why have a partner at all? Why not have a sexual life with oneself and no further bother? Why can't one have a relationship with oneself directly without the intervention of a sort of mental or physical midwife? It seems as if we need to be able to 'bounce off' another person, to have something which could reflect back what we say before it becomes comprehensible.

Q: It is an interesting fact that if you simply play back a videotape to a patient or a trainee without another person there to bounce off, it doesn't usually accomplish anything. If it does accomplish something it is negative. There is evidence to bear this out; patients tend to get worse when they are exposed to a videotape with no one else present.

B: That certainly points up the problem just mentioned: Why does the presence of a person matter? Why not just have a piece of machinery? If one could get near to being a dispassionate machine which simply reflected back what the patient says, I don't think the patient would get anything out of it at all. In fact, patients often try to assure themselves that you are capable of losing your temper and behaving badly. It is only when they find that you are capable of it – but don't do it – that it begins to mean something.

Q: Could you explain how the patient finds out that you are capable of losing your temper or behaving badly without your actually doing it?

B: I don't think I could, but I think the patient could, especially one who, as a method of trying to find out if you are really capable of being hostile or not, is extremely provocative for session after session, month after month. I don't think any patient is unaware of the analyst's ability to wear the correct 'uniform', the correct manners, the correct character, the correct qualifications – all that can simply be a cloak for the real person. Patients are not easily taken in by it – they may agree, they may feel capable of compromising as if to say, "I know you are paid to talk like this and learn all this stuff; I'll agree that you are quite a decent fellow". You enter into a collusive relationship. But the psychotic patient is somewhat exacting; an interpretation which is *approximately* right is not 'corrected' as a neurotic patient will do. A neurotic patient will help you, will allow you to be 'off the beam' and yet enable the beams to fuse.

Q: If the analyst's interpretation is not exact does the psychotic patient feel as if he were alone in the room?

B: The answer to that may depend on being able to differentiate one kind of psychotic patient from another. Some of these psychiatric diagnoses like the difference between 'schizophrenic' and 'manic-depressive' may refer to something which is so crude that it can actually be verbalized, conceptualized in this way. But these categories of

diagnosis which are at present available to us are not good enough to deal with the subtleties of the situation you are talking about. In fact nothing short of continual observation is going to solve these problems.

Q: There is a notion that there is nothing more to psychotherapy than that the patient goes to a therapist whom he respects, not feeling much respect for himself; that therapist communicates in some way over a long period of time his respect for the un-self-respecting patient who fights it every inch of the way, either by discrediting him so that he is less respectable, or discrediting whether or not he is truly respected, until finally the patient gives in, believes in the therapist's respect and ends up respecting himself. That's the grossest oversimplification one could come up with. What more do we know that could offset that as being the fundamental process?

B: The relationship with the analyst is only important as a *transitional* affair – it would be useful if the word 'transference' were used in this more polyvalent sense. Unfortunately patients can terminate the relationship because of one of these transitory cures. They get some relief and say, "Well, thank God for that", and pack it up at that point. They have so little experience of real relief that they are only too thankful to get anything at all and to call it a day – and to play on the fact that so is the analyst. "Doctor, you're marvellous. I feel a new man – good-bye." There you are – such a nice conclusion you might as well stop there.

Q: I have been thinking about your reference to answers being stop-gap measures in stifling curiosity and how difficult the resolution of the choices is when, as a parent for example, we give an answer like "No, you can't" but still want to foster the environment where there is self-respect in continuing curiosity.

B: It is so difficult to see what is the equivalent of 'full term' in mental development. What is the moment at which the patient can safely leave, as it were, the analyst's inside? In analysis, or in ordinary medicine for that matter, the doctor can be very cautious. He can lay down rules; the patient *must* go on with the treatment; or *must* stay in hospital; or must *not* start work yet, and so on. That can be carried to extremes if the doctor is unwilling to run the risk of being responsible for a failure. So he can hinder the progress of the patient towards independence. But there must be a right moment for leaving

hospital, or a right moment for leaving an analysis – being neither seduced into an early and premature termination, nor frightened into continuing further.

Another problem arises if the patient is extremely unaggressive and fears doing anything we would call 'showing initiative'. This makes me think that the full-term foetus has something to do with the time of delivery; it can get so frightened of precipitating a catastrophic or disastrous event that it initiates nothing. Later on the patient learns how to be independent, but this fundamental fear becomes established as an archaic fear, something which is unconscious, some-thing which is not known. Outwardly the person is brilliant, clever, so successful, so marvellous, until one day there is a disastrous outburst. The patient is alleged never to have shown the slightest signs of disturbance, so it is incomprehensible. There is no explanation for this extraordinary outburst which is particularly liable to take place at any of these times of 'turmoil' or 'turbulence'.

4

Bion: Seeing patients many times as we usually do, it is difficult to achieve that degree of naïveté in which we can see them each time as if we have never seen them before. It is easy to think, "Oh, here's the same old stuff again – yesterday, the day before that, for weeks, months, years". It cannot in fact be so because tomorrow the patient we saw yesterday, or last week, month, or year, will not be the same person. We should get as near as possible to feeling that it is the first time we have ever seen that patient. It is difficult because we always feel that we ought to know his history and so on and so forth – a backwash of our own medical training. It is useful for two or three sessions, but after that this information which one has from hearsay is unimportant. From that time on we should be launched out into a different realm altogether – not the realm of the patient's history.

Questioner: You are really saying that you don't have to take notes. Each time a person comes in he is a new person and it is only what is being presented at this moment that is important.

B: Yes. As I said before, Plato pointed out that language is extremely misleading – it appears to be precise and exact, but in fact it is no more exact than painting or drawing. A painting doesn't tell you anything – it has to be interpreted. Charcot, by whom Freud was impressed, said you have to go on looking at a patient until a pattern begins to obtrude. In physical medicine a doctor's sense of touch, smell and so on, should be so acute that he doesn't read books but reads people. With regard to these mental symptoms, what can we say? Neurotic? Psychotic? It doesn't tell us anything. The difference between people appears to be so striking that it seems to demand a description; so we resort to this crude division. We have to make the

assumption that there is such a thing as a mind. I don't know what evidence there is for it – it may be completely erroneous. In Homeric times the mind was thought to be located in the *phrenes* – the diaphragm. It seems a sensible, scientific idea. It is obvious that if you start breathing deeply the diaphragm, working up and down, makes you breathe in and out. And if you see somebody else doing it you think, "What's all this about? Is he trying to come at me to knock me out? What's he up to? What's all this panting about?" Then Democritus of Abdera began to suggest that the mind had something to do with this useless mass, the brain, for which no function had been found. The idea that there is a mind still persists, but we go further. Freud suggested that when a person 'forgets', the gap – the empty space of our ignorance – is so disliked that it is filled with bogus ideas, paramnesias. But since we know nothing about the mind, why isn't the whole of Freud's work an elaborate paramnesia constructed because he couldn't tolerate being ignorant of it? I am trying to get back to the basics – even questioning the existence of the mind itself. Once we are convinced that nothing short of such a supposition is going to meet this puzzling situation, then we can start making distinctions about what appears to be the behaviour of the mind. Supposing there is such a thing as a disturbed or disordered mind, where does the illness come from? What is the 'focus of infection'? Is it helpful or reasonable to borrow that term from physical medicine? Does it give us a clue? Most people learn to behave as if they are well. They find some way of training their bodies so that they can become athletes, surgeons, dentists, and consequently nobody notices there is anything wrong with them. What would we think if we knew someone carved holes in human beings – if we could not excuse the behaviour on the grounds that he was a surgeon? How odd it would look to see someone drilling holes in people's teeth – unless there was some 'rational' explanation. It is possible to find a rational explanation for anything, but in contrast to that it would be helpful if we could see what was irrational. Then it might become easier to understand why a successful surgeon who has done surgical operations for years suddenly has what we call a 'breakdown' and cannot face the operating theatre. Is it breakdown? Or break-up? Break-in? Or break-out? Or breakthrough? In other words, what direction is the person going in? Is the surgeon seeing something he has never allowed himself to see before – how cruel, how brutal, how violent he

is? Using the analogy of ordinary medicine, it is as if there were some focus of infection which has now begun to emerge into the skin. The mind, unfortunately, has no skin as far as we know, although Freud talked about the id, the ego and the superego – a crude, but shrewd subdivision of the mind into various parts.

Q: As you have been talking I have been going over and over a session I had today, and thinking that I had very little idea of what was going on. I would rather do anything than acknowledge that.

B: Yes – so would the patient, and so would we all. It is a basic characteristic which probably helps to explain why we know as much as we do today – it is so difficult to tolerate being ignorant, and so much easier to scrape up an answer which is a more or less rational explanation of our behaviour in order to justify our title of 'psychiatrist' or 'doctor'. I don't think there is anything particularly wrong with it except that it is a nuisance to oneself. The moment somebody comes into your office you at once feel the pressure on you to be the person who knows the answers.

I mentioned before a quotation of Maurice Blanchot, *"La réponse est le malheur de la question"*, which I could translate – again a matter of interpretation – "The answer is the misfortune of the question". Putting it into different terms once more, "If you have any curiosity it is answers which put paid to it", or "knowledge is the disease of ignorance". In any of these situations where you are in a tight corner you always want to find a way out – and that seems perfectly reasonable. When you don't know the answers – a desirable state of affairs if every session is to be an entirely fresh one – you have to find new words.

Q: If you think every session is fresh and new, why bother with history taking at all?

B: I don't. I have kept notes from time to time, but when I have looked at them later what do I see? 'Tuesday – !' What on earth is it all about? I have no idea. I should like to take a note which at least reminded me of something. So the first requirement is to be able to see, hear, smell, feel something to be reminded of – but what notation to use to write it down I don't know. If I were an artist I might draw or paint it. If I were a musician I might compose a musical work. But what are psychiatrists to do about it?

Q: Why do we want to be reminded? Why does it seem important over a period of time to be able to remember?

B: It is hard to know. The most impressionable years of your life are devoted to trying to forget what you are really like. You are helped in this – "Don't do that", we say to the baby, and oddly enough the baby seems to understand. Don't do this. Don't do the other. Don't, don't, don't – that is the operative word. According to the psychoanalytic view there is some reason for remembering, but it goes against what has been learnt very thoroughly, at the most impressionable time of one's life. It may not be of the slightest importance that you wanted to suck your thumb some time in your life, but you can't forget anything which you can't remember. So before you can forget it, before you can discard it, you have to bring it up into consciousness again.

Q: Recently I have been thinking, reflecting after the analytic hour, sometimes during the hour, on how to direct the patient's attention simply to what he has said or the way he has said it. What are your thoughts about this?

B: In order to pick up these remarks, these signs of some mental archaic element, we have to be in a peculiar state of mind; the margin between being consciously awake, able to verbalize one's impressions, and being asleep, is extremely small. It is easy to be in a state of mind where you slip over into sleep, actually in the office when you are supposed to be working. It is equally easy to slip over into a state of being horribly intellectually awake. The border between the two, the correct state of mind, is very difficult to achieve; one is always oscillating above and below it. Being on the right wavelength, which has to be experienced to be recognized, is unfortunately comparatively rare. Nevertheless most patients are able to put up with the rarity of it on the off-chance that we may sometimes succeed.

Q: More and more pressure is being applied to the medical and mental health professions to provide evidence, to the various agencies that fund health care of quality, that there is some actual effect taking place from whatever we are doing for our patients or clients. Do you think we are ever going to reach the point where we can demonstrate in any objective way the effect of psychotherapy or psychoanalysis in the same way that people in other sciences are able to demonstrate effects?

B: I have great difficulty in believing that it will be so. It seems to me that the situation is so urgent that it is a matter of grave doubt as to whether we shall not destroy ourselves before we ever get there.

We think we can formulate the correct diet for the human being's digestive system. I don't think anybody has got anywhere near to prescribing what the mind ought to be fed on. I know of no book on mental dietetics; I hope there won't be until somebody knows something about it. But usually the book comes first and people find out about it later on – the premature and precocious theory or cure.

Q: I seem to recall some books from the early part of this century, religious books on spiritual diets, mental hygiene, prescribing rigidly what people should think about from morning to night in order to be healthy.

B: Yes; the idea that there are things about which we might have second thoughts is felt to be repulsive.

Q: What do you think of Skinner's idea of setting up a whole community?[1] From birth the child is taken over by the community?

B: If it is to serve as a method of watching and learning about the process of growth I would be in favour of that, but in so far as it involves imposing rules, it is like forming a shell which you then have to break through. We do form these shells anyway – and go on doing so. But the shell can become so thick, so strong, so powerful that the thing inside cannot develop. Any institution has this fault; any institution of human beings that I know of and of which I have some evidence could be regarded as dead. In so far as it is dead it is quite amenable to laws, by-laws, theories which are codified. These same institutions have inside them individuals who are not dead; they, the living objects, go on growing within the community which is rigid, dead, it obeys the laws of inanimate objects. The growth of these individuals inside the institution will sooner or later put pressure on it – it will start bulging out. Then the danger is a double one – either there is such a rebellion against law that the whole society becomes a lawless one, or it defends itself by becoming very rigid so that the growing individuals inside it cannot continue to live in that kind of dead institution. If this community of individuals is still alive then they increase the pressure on the institution which will then *have* to revise its laws or face disintegration.

Q: There is a community of people who are trying to be innovative, especially those in the arts. This incorporates a very large group,

---

[1]The Utopian community described by the behaviourist and psychologist B. F. Skinner in his 1948 book, *Walden Two*.

because I feel that it includes professions such as yours as well as music, plastic arts and so on. Disregarding the dilettantes within that grouping there are some who feel uncomfortable within the 'dead' rules, as you call them, and find themselves in the position of breaking out. Art is called anything from regression in the service of the ego, to various neuroses. Adler calls it 'compensatory theory of creativity', the production of art, science and so forth to compensate for one's inadequacies. The fear of death, of wanting to gain immortality and all these other clichés sound very clever, but under careful examination they don't hold up. I would be interested to know how you feel about that as a means of communication and its validity.

B: It would be helpful if it could be recognized that all these various disciplines – music, painting, psychoanalysis and so on ad infinitum – are indeed engaged on the same search for truth. Talking as we are here, we can split it up as I have just done; it is very useful for purposes of verbal communication. If all we wanted to do was to communicate verbally that would be fine. We could stop there; we could say, if it can't be verbalized, out with it! Get rid of music; get rid of painting. But if you are tolerant then you have to see the possibility that the painter can make progress which is not possible for somebody who is capable of talking only one kind of language. The fundamental problem is, how soon can human beings reconcile themselves to the fact that the truth matters? We can believe whatever we please, but that doesn't mean that the universe is going to suit itself to our particular beliefs or our particular capacities. It is *we* who have to do something about that; *we* have to alter to a point where we can comprehend the universe in which we live. The trouble is that supposing we reach that point our feelings of fear or terror might be so great that we couldn't stand it. So the search for truth can be limited both by our lack of intelligence or wisdom, and by our emotional inheritance. The fear of knowing the truth can be so powerful that the doses of truth are lethal.

Q: You spoke earlier of the therapist missing cues given out by the patient. I have been thinking about the willingness of the therapist to be fooled or to escape this knowledge of what is about to happen. A lot of psychological autopsies have been done lately examining the actions of the patient, attempting to piece together what he has been doing or thinking. But I haven't seen any studies about the

overwhelming fear that may have been operating in the therapist at the time. We want to feel that everything is all right and may therefore be looking the other way.

B: That's right – "All is for the best in the best of all possible worlds" – Doctor Pangloss.

Q: Our fear may be just as great as the client's.

B: It certainly is. The only hope is that we may be capable of standing the stresses of it – nothing can demonstrate that except trying it. In analysis the important thing is not what the analyst or analysand can do, but what the *couple* can do. In marriage it doesn't matter how much the two individuals can do; there should be something the couple can do where the biological unit is two, not one. The two people who get together don't know anything whatever about marriage, nor about what sort of people they are going to turn into; it is another situation filled with the unknown. Can that marriage hold together long enough for the couple to learn a certain amount of wisdom? Analysis is an attempt to introduce something which is not so important, so fundamental as marriage but is an extension, shall we say, of playing games like 'Fathers and Mothers' which we hope has a value for the future.

Q: Could you talk about the three basic assumptions – dependency, pairing, fight–flight – in your group work.

B: They are crude constructions, generalizations. I think they have something in them because they are all basic, fundamental, primitive. For example, 'fight/flight' could almost be put in terms of the chemistry of adrenaline or glandular relationships; 'dependence' as that of the mouth on the breast and on sucking it. The general theory may be good enough for wide application, but in practice, in the world of reality, we are always up against the precise and particular instance, not the general. I am sick and tired of hearing psychoanalytic theories – if they don't remind me of real life they are no use to me. An application of a theory about dependence is no good to me unless it reminds me of something which I can see at any time in the world in which I live.

Q: I would like to hear more about what you call 'valency'.

B: That is borrowing a term from chemistry and physics. The relationship between two people would depend on their having various characteristics of which two or more came together – not

the whole lot because there would then be no valency available for relationships with people other than themselves; that would be a marriage so perfect as to be absolutely unstimulating. There ought always to be some valencies left over available for attachment to something that hasn't happened yet. In a situation where we are simply Mr and Mrs Know-all there are no valencies – nothing to catch on to anything that is unknown.

Q: Does the patient come to us saying, "Solve my problems"?

B: Of course; always this pressure on the analyst to know all the answers; always the pressure on the leader to know all the answers – which would seem to be the death of the community if it could be so. But that would carry with it revolt against the leader who knows everything and there would therefore be no chance for the exercise of curiosity. In the universe in which we live the opportunity for curiosity seems to be boundless – so much so that we try artificially to put a boundary round it. We try to stifle this curiosity by producing a boundless number of theories so as to be able to feel "This far and no further". Alternatively, there is a revival of thalamic fear – the fear which is so powerful that it makes thinking impossible.

FOUR PAPERS

1976/1979

Four Papers was first published in 1987 in *Clinical Seminars and Four Papers*, by Fleetwood Press, Abingdon. It was reprinted in 2000 as Part Three in *Clinical Seminars and Other Works*, edited by Francesca Bion (London: Karnac Books).

'Emotional Turbulence': from *Borderline Personality Disorders,* edited by P. Hartocollis (New York: International Universities Press, 1977).

'On a Quotation from Freud': from *Borderline Personality Disorders,* edited by P. Hartocollis (New York: International Universities Press, 1977).

'Evidence': from the *Bulletin of the British Psychoanalytical Society* (1976).

'Making the Best of a Bad Job': from the *Bulletin of the British Psychoanalytical Society* (1979).

EDITOR'S INTRODUCTION

These four short papers were published between 1976 and 1979. I shall make a few comments on the first of them, and on the last. The first of the four has the title 'Emotional Turbulence', a concept at the heart of Bion's ideas concerning learning and growth. In his 1965 book *Transformations* (see Volume V) Bion had linked emotional turbulence to the inevitable pain of inquiry. Bion wrote of column 2 of his Grid as specifying the acceptance of an answer known at some level to be false, in order to evade the pain of leaving the question open and allowing an evolution, with the possibility of disruptive growth of the mind.

He had written elsewhere – for example, 'São Paulo 1978' (Volume VIII) – about the 'emotional storm' resulting from the coming together of two personalities in the analytic consulting room,[1] and, like Grinberg (1957, 1962, 1979), he had emphasized a particular and clinically important aspect of countertransference induced in the analyst under conditions of intense, powerful projective identification stemming from the patient:

> As a result of the pathological quality of this mechanism, the patient is able to induce different roles, affects and fantasies in the analyst, who unconsciously and passively feels himself 'carried along' to play and experience them. [Grinberg, 1979, p. 226]

This harked back to Bion's clarification,[2] using the group situation, of the relationship between projective identification and countertransference.

---

[1]Bion had been struck by Freud's use of the term in *The Interpretation of Dreams*: "all of this combined to produce the emotional storm which was clearly perceived in my sleep and which raged in this region of the dream-thoughts" (1900a, p. 481).

[2]See Volume IV (*Experiences in Groups and Other Papers)*, p. 213.

The last paper of the four – and Bion's final paper – had the apparently sombre title, 'Making the Best of a Bad Job'. The phrase is very Bion and is not as melancholic as it might seem to be when read out of context, as is also made clear in Bion's use of it in a response to a question about countertransference two years earlier, in New York in 1977 (see Volume VIII):

> My understanding of the correct meaning of the term 'counter-transference' is that it is *unconscious*; since it is unconscious, the analyst does not know what it is. So I have to put up with the fact; it is to be hoped that I am aware that I have there elements about which I can do nothing unless I go to an analyst myself and get them dealt with. It is a question of making the best of a bad job. The bad job happens to be me. I cannot get thoroughly analysed – I don't think there is such a thing. It has to stop some day; after that I have to make the best I can of who I am.

Near the beginning of this 1979 paper, Bion reminds us of something he had addressed before he became an analyst, in his 1940 paper, 'The War of Nerves' (see Volume IV). It is that in war the enemy has the intention to instil terror to prevent us from *our* objective, which is to continue to think clearly enough, no matter what disturbance comes our way. Bion was likening this situation – of which he had ample personal experience – to the anxieties inherent in scientific inquiry, including the analytic situation; he went on to claim scientific status for a series of statements for which he knew he could not provide convincing evidence. Bion begins with the fact that both the patient and the analyst have something called a Self, or a personality. He uses the adrenal glands to pursue an analogy concerning how physical structures may develop from the anticipation of having to provide mechanisms for necessary functions – and his list contains both the behavioural components of flight–fight, the basic sensory functions, and the ego-function of thinking: "a bodily anticipation making possible the later *functional* operation of a mind." The reader might like to compare this idea with Freud's pre-psychoanalytic account of the inception in the infant of a mental system, initially through the essential help of an outside object – the mother. This can be found in the 'Project for a Scientific Psychology' (Freud, 1950 [1895], p. 318).

Bion considered communication within the self from a non-Cartesian position. To glean what this might be, Bion made a plea for the analyst not to narrow his or her attention, but to be aware more of the totality of impressions. The concept of O is hidden in the folds of his

writing here. He cautions us to be oriented not just to the *content* of the communications, but also to the *process*, the 'music'.

The playwright Enda Walsh has expressed something almost identical: "A lot of the time I want to turn the volume down on all these words, and just trace the characters' emotional connection to what it is they are talking about."[1]

Clarifying what he means by the term 'scientific' in this context, Bion contrasts 'real-ization' (making real) with 'ideal-ization'. He brings out the difference clearly by defining the latter as: "the feeling that the world, the thing, the person, is not adequate unless we alter our perception of that person or thing by idealizing it". Real-ization, he writes, stems from a similar dissatisfaction, but in the opposite direction, "when we feel that the ideal picture which we present by our statement is inadequate". Therefore, argues Bion, we should consider that polarity as one of the dimensions of the way in which Self communicates with Self. That is to say, what pictures does it provide intrapsychically?

The paper takes more turns before ending with a warning about the hazards of the respectability and authority of knowledge. Bion suggests here that it is for each new generation to consider afresh the extent to which ancestor-worship is operating against exploring living personalities, serving instead to erect and strengthen barriers to new understanding. His final sentence, "That war has not ceased yet", preserves an echo of his final sentence in the *Memoir of the Future*:

> There are no labels attached to most options; there is no substitute for the growth of wisdom. Wisdom or oblivion – take your choice. From that warfare there is no release.

Four Papers

INTRODUCTION

Prior to the 1987 edition of *Clinical Seminars and Four Papers*, these four papers had not been published in a book of Bion's work. The first two, 'Emotional Turbulence' and 'On a Quotation from Freud', were included in *Borderline Personality Disorders*, a collection of papers given at an international conference in Topeka in March 1976 and published by International Universities Press, New York. The other two papers, 'Evidence' and 'Making the Best of a Bad Job' (the last paper Bion wrote), originally appeared in the *Bulletin of the British Psychoanalytical Society*. I am grateful to I.U.P. and to the Editor of the Bulletin for their permission to reprint.

Francesca Bion
Abingdon, Oxfordshire
August 1987

Emotional turbulence

1976

The entity known to members of the medical, psychiatric, and psychoanalytic professions under the usually adequate designation 'borderline patient' or 'borderline psychotic' is in no way familiar to laymen and workers in other fields. It therefore seems possibly illuminating to approach the conference's topic as it usually presents itself to the medically unsophisticated and to work from this to the medical definition.

We are all familiar with the term, 'latency'. I want, for the time being, to forget the customary usage because it is easy to focus on latency rather than *what* is latent. I find it useful to consider that, in latency, what is latent is *emotional turbulence.* When the quiet, cooperative, nicely-behaved boy or girl becomes noisy, rebellious and troublesome, the emotional upheaval rapidly ceases to be limited by the physiological boundaries of what we call John, Jack, Jill or Jean in his or her corporeal frame. Into this emotional field the psychiatric worker enters. His problem can be seen in its hideous, practical reality when he is called upon – usually too late – to pronounce on the admirable (though to exceptionally intuitive authorities *not* so admired), docile child, and strongly suspects schizophrenia; or when he must judge the depression (or admired liveliness) of a manic-depressive psychosis. In choosing 'emotional turbulence' I include its counterpart and opposite.

Leonardo's *Notebooks* contain many drawings of water swirling in turmoil, of hair in disorder. Milton, in *Paradise Lost,* writes in his invocation to Light at the start of the Third Book, 'Won from the void and formless infinite.' We can think of other works by painters, poets, priests, which call up similar pictures or thoughts from our own experience. It is not my intention to interpret, psychoanalytically or

otherwise, these instances of human creation. I wish to recall them so that you may invoke similar images from your own scientific, artistic, or religious inheritance – whatever is for you most evocative of a period of mental turbulence similar to that with which psychoanalysts deal. I do not stress adolescence because, for most psychoanalysts, that conception is too strong; latency is too weak. I would that analysts recall periods of mental turmoil that have evoked the most turbulence in themselves.

To clarify 'too strong', I take the term 'caesura' from Freud's *Inhibitions, Symptoms and Anxiety* (1926d [1925]): "There is much more continuity between intra-uterine life and earliest infancy than the impressive caesura of the act of birth would have us believe." Freud's summary can itself be described as one in which the 'impressive caesura' is *too* impressive to allow us to suppose that the foetus might have a proto-mind and personality, or could develop its proto-mind into a mind after birth.

Repression, said Freud, is *not* an event that takes place once; the caesura of birth, like the caesura of death, is impressive because it apparently takes place only once. It is hard to observe that repression is a kind of death. Breakdown, neurosis, psychosis may, in their turbulence, be difficult to discern, but they may be a birth inseparable from repression and death. In analysis we often have reason to think that we cannot penetrate the impressive caesura of resistance or its varieties.

Can any growth take place without repression? Is progress inseparable from repression of the previous state? Does any thought occur without resistance to the thoughts *not* selected? Is there any feeling or idea that is not subject to resistance as an inevitable part of choice or chance? Is anything separable from anything else in the way that one word can be separated from another, or one physical body from another?

The problems of decision are reactivated as emotional turbulence, and as a cause of, or precipitation from it. On occasions when the turbulence is great enough, it is dramatic, as at birth, death, adolescence, or the onset of senility. Decisions are evolved in the community, family, group and individual; people with a psychoanalytic vertex have committed themselves to thought and discussion. The decision, and the discussion of it, entails a considerable preceding process of maturation. A patient, whether a child or not, requires some degree of

precedent experience. There are limits, even if we do not know what they are, beyond which the analysand is too young or too senile, too retarded or too precocious. We consider only what lies between these somewhat shadowy precincts – the limits of wavelength that bind the polyspectral 'area'.

There must be choice; this entails being tolerant enough to view the emotional turmoil. The turmoil observed has to be split – artificially, verbally. Some individuals appear unable to make these verbal splits without feeling that they have in fact physically split. The next element in choice depends on chance, that is on some force other than the conscious human being who chooses. The matters dictated by chance cannot be discussed by us in advance because this is an open-ended problem confronting any group, any individual, any society. In analysis it is possible to discuss what is going on between the two people who are participating: the analysand can keep the analyst informed, and the analyst can do his best to interpret the information made available to him. The patient, who is usually in a state of turmoil, has first to decide what he will choose to talk about. Patients frequently say, "I can't think of anything to talk about today", or, "I have an awful lot to talk about, but don't really want to talk about any of it." These statements have their counterpart in a group where the members seem uncertain what to discuss. Sometimes one particular person is anxious to put forward his view; at other times nobody wants to say what he is thinking about, and the group becomes duller and duller, less and less communicative. The person leading the group must then consider what he should do with the situation which is unknown to him but which the chance of that particular session presents to his inspection. Here again there is chance, namely, events discernible in the turbulence. The individual in analysis may not be communicative, but he is nevertheless upset. It is wise for the analyst to assume that people do not spend time and money on analysis unless they are disturbed – no matter how smooth, straightforward, and apparently simple the view they present for the analyst's inspection. The same applies to the group; the individual members certainly have problems. But a group inspection provides a chance to see what interaction there is between the emotional situation that is apparently restricted to the individual, and the way it spills over and affects other group members.

One disadvantage of the group situation is that seeing, say, six or ten people at the same time leads one to suppose that there are six or ten discrete personalities present. In other words, the distinct physiology of the participants is so dominant that one is liable to assume that the personality is similarly bounded by physical appearance. The 'dramatic' effect of having the personalities present makes one suppose that the important thing is what any individual participant is saying or doing – another caesura. A similar situation exists with the individual who, it is assumed, has no problems dating from before birth – this dramatic event appears to present a caesura which cannot be penetrated.

In the Greek city state, where the numbers were small, democracy could operate; every individual was able to know sensibly what was going on. The people could collect in a forum and each individual could exercise his senses on material presented for his inspection. In small groups it is possible to be available to the forces that are operative; the reactions of the group can be seen. In addition to paying attention to what is actually said, we can be open to whatever else is going on – tones of voice, smiles, gestures, silences, and overt signals from one person to another. A wide spectrum of events is thus open to our inspection; there is a turmoil of communications. But, however chaotic the situation, however psychotic or neurotic the phenomena seem to be, the analyst must be sufficiently tolerant of them to be able to observe what is going on. He is then faced with the problem of what, if anything, he proposes to say – saying something involves choice and the events therefore have to be ordered. What takes place is an artificial splitting of the total situation into various elements, an ordering of these elements, and a reintegration to bring these perceptions together again.

The expectation of the group can be so intense that it can hardly wait to hear what is going to be said. This expectation stimulates a great many feelings which can be so intense that the group becomes resistant to any emotion and falls silent. Expectation has been overaroused (including expectation of disappointment or disillusionment); a barrier (resistance, prohibition, caesura) is erected to protect the solution of the previous problem, to separate the present from the past, the future from the present. This barrier can become impenetrable to further development, but on the other hand, the group *can* develop if the caesura is an illuminating idea.

This situation is inadequately described by terms like 'caesura', 'resistance', or 'cure'. A polyvalent word is needed to bring together the actual elements, or a representative number of them, involved in one caesura. What I am describing signals the cessation of an epoch; the patient feels 'cured' by an interpretation (or misinterpretation), or sees some point which hitherto has been obscure. The tendency is for the patient to want to say, if he can verbalize it at all, "That settles it now. I don't want it to be unsettled." Having achieved illumination, he does not want any more. This is more observable in a group when it is presented with an idea which it has not had before. If the members see the point, this stimulates closure, converting the open-ended problem into a closed solution, settled once and for all. But there is no solution once and for all; each solution opens another universe. The situation, except for that point where a breakthrough in analysis has occurred, is wide open again – a vast, open-ended problem. The individual is now free to learn more, but unless he wishes to do so it cannot from his point of view be regarded as a satisfactory 'cure'.

To turn to a few questions: without any suspicion of Socratic irony, I would make it clear that they are serious ones. And although I know they are simple questions, I am aware that the answers may be unexpectedly difficult.

As an example of the simple answer to a question, I offer a joke illustrated in *Punch* magazine. A small boy draws an adult's attention to a lark singing in the sky. He states, "Hi, mister, there's a sparrer up there an' 'e can't get up an' 'e can't get down an' 'e ain't 'arf 'ollerin'.' This discovery made by a small boy gives information which might otherwise escape attention.

Another anecdote taken from the same source: a small boy speaking to his father says, "What's that, Daddy?" The answer: "A cow." "Why is it a cow, Daddy?" Answer: "Because his Mummy and Daddy were cows." "Why were they cows, Daddy?" These three simple questions, asked one after another, take one directly into realms of complexity which include problems still unsolved. This is true not only of the questions but also of the answers, because like all really good answers, they stimulate still more questions. Any good solution to a problem causes the subject illuminated to reveal further questions and further problems.

A simple question: when is a human being born? Individuals may give me an answer in the particular instance of their own birth. I

would then ask: when was your personality born? When did you first see light? When did your optic pits become capable of seeing light? Were your optic pits susceptible to pressure, giving the impression of light adequate in the sense of stimulating the sensation of sight, inadequate in the sense that what you 'saw' was not what is called adult or mature sight? I could ask a similar question about the auditory pits.

Some more questions and answers: what are you doing? Thinking. How do you know that you are thinking? My phrenes are going up and down. That answer is plausible; anybody can see that when a person begins to breathe heavily, in and out, it is reasonable to suppose that that state is caused by the diaphragm, as we call it, or *phrenes*, as the Homeric Greeks called it. Like the lark, it has an obtrusive characteristic; the answer is comprehensible, it would seem to be correct. How does somebody think? Their phrenes go up and down. It is a good answer in this respect: it stimulates still further questions. In the time of Democritus of Abdera people began to suspect that the inert and somewhat useless mass of stuff they carried about in their skulls – the brain – was connected with thinking; thinking might be a function of that material which seemed to terminate the parasympathetic, sympathetic, and central nervous systems.

During the Second World War I encountered the Matrix Test, imposed on members of the British army. Men were expected to choose one pattern out of several to complete a page of incomplete patterns. The number of correct answers was matched against the number of failed answers, and it was thereby supposed that you had a rough-and-ready intelligence test. There were complications. One man, for example, was certain that the tests could not be so ludicrously simple, and proceeded to measure the patterns offered and the vacant spaces. Consequently, his score was zero. Theoretically this would mean that he had a very low intelligence. If this man's personality is assessed psychiatrically, the problem becomes more complex. He may not be stupid, but why is he so suspicious? Why can he not believe that a simple answer is the correct one?

Ignorance is filled with knowledge; there are numerous answers to the questions that arise if it is supposed that the human animal has a mind. Why is it a cow, Daddy? And why is Daddy or Mummy not a cow? As a psychoanalyst I could fall back on articles by Melanie Klein, Abraham, and others too numerous to mention. But I will

first fall back on a simple answer. People do not often deliberately and consciously withhold information when they are expected to provide it. That would be a conscious example of presenting the inquirer with a blank space. There are, however, certain failures to answer which Freud considers to be unconsciously withheld – that is, they are not deliberate attempts at falsification, deception, and evasion. There are other occasions when a person exhibits doubt, or presents an answer that seems to be unsatisfactory. Freud calls this false memory, intended to fill the space left empty by the amnesia. This suggestion is fruitful; it leads to more questions and inquiries which I would extend still further. If it is true that the human being, like nature, abhors a vacuum, cannot tolerate empty space, then he will try to fill it by finding something to go into that space presented by his ignorance. The intolerance of frustration, the dislike of being ignorant, the dislike of having a space which is not filled, can stimulate a precocious and premature desire to fill the space. One should therefore always consider that our theories, including the whole of psychoanalysis, psychiatry, medicine, are a kind of space-filling elaboration not in essence dissimilar to the belief that the lark in the sky is "a sparrer that can't get up and can't get down and ain't 'arf 'ollerin'." In other words, the practising analyst has to decide whether he is promulgating a theory, or a space-filler indistinguishable from a paramnesia.

Anybody who reminds the human animal that it knows very little is likely to be unpopular. Human beings clamour for some kind of authoritative statement to take the place of both ignorance and the exercise of curiosity; they hope, in that way, to put a stop to disagreeable feelings of ignorance and the repetition of the questions. The repeated questions may even be what is known as repetition compulsion. But repetition compulsion may in fact be a spark of human curiosity which has hitherto failed to be extinguished by any authoritative statements from whatever source.

We are familiar with being expected to provide the answers to questions. In examinations, as candidates, we are invited to provide answers to the questions asked, and our examiners are usually, and plausibly, thought to be entitled to fail us if we do not know those answers. But here again, one wonders whether this is a kind of disguise – anger at being frustrated, at being unable to be presented with a plausible answer to the question we ask and are asked by other

people. We identify both with those who ask questions, and with those who are supposed to know the answers. I mentioned that I did not wish to be suspected of Socratic irony, not least because Socrates came to an unfortunate end – a result of asking questions. It is possible that the same danger will arise if our answers make open-ended what appears to be closed.

In view of the advances made by the human monkey who has become powerful enough to blow himself off the face of the earth, the situation is urgent. It is a race between his capacity for inhibiting knowledge – his own and other people's – and his capacity for advancing his ability to make 'tricks'. Walt Whitman wrote, "I am the teacher of athletes. He who spreads a wider chest than my own proves but the width of my own. He best honours my style who learns under it to destroy the teacher."[1] Students may learn today not only through what they are taught by their universities, but also through themselves.

I should be sorry to give the impression that because I am not filled with panic I therefore tell a harmless bedtime story. I would, without alarm, draw attention to a situation which is now one of urgency. It is a question of whether the paramnesias, the answers that are immediately comprehensible, that can be used to fill up the space of our ignorance, mislead us into extreme danger; whether the powers of the human mind match its destructiveness. So far the human being has survived and preserved a capacity for growth.

The gifted person may be able to draw and thus communicate visual images to others, to those with less capacity to intuit. Leonardo's drawings of hair and water give a good idea of what turbulence looks like. Mental turbulence, whether one's own or that of the community in which one lives, is much more difficult to depict; its existence and significance cannot be understood if the turbulence is not observed. Today almost any newspaper displays signs of turbulence; it exists in areas which have hitherto been regarded as civilized. If turbulence is demonstrated, the reply is likely to be, "What about it? We all know this." That is an example of the caesura; it is hard to penetrate what we 'all know' and to suggest that there may be something that has

---

[1][The lines quoted here are from Part 47 of Whitman's 'Song of Myself', an American epic poem with which Bion, as a strong athlete and swimmer himself, identified. *Ed.*]

not yet emerged from the turbulence, just as there may be something – we do not know what – that led to the turbulence. Are we then to inhibit the turbulence? Or are we to investigate it? From a certain point of view it would seem simple to answer that question. Universities and learned societies consider it wise to investigate, to exercise curiosity on the observed turbulence (the problem) *and* the theory believed to be a satisfactory explanation of the problem. Curiosity has itself to be under scrutiny while being exercised; we must not be directed towards understanding other problems by inhibiting observation of our own curiosity.

In a group with a diversity of opinions and views available, a diversity of characters we can observe and be observed by, what procedure should we adopt? All the members of the group represent different states of mind; each state of mind may be seen as an integer, an integrated whole, as something we might describe as human nature, human mentality, or human character. We could investigate it more easily by 'splitting' these different 'vertices' into states of mind corresponding to the anatomical structures of the individual human beings. But is personality bound by the physiology of the person, or is there an integration corresponding with the statement, *Vox populi, vox Dei*? If there is a cultural characteristic, it might express itself by favouring certain thoughts and disfavouring others. A caesura, difficult to penetrate, is created. (It is curious that this term, 'caesura', was misprinted in the original paper by Freud as 'censure', so that it was even then – accidentally of course – unconsciously described as a censor, an inhibition.)

Recently the primitive artist appears to have penetrated the caesura between cultivated and primitive; the cultivated artist seems prepared to learn, or allow himself to be aware of, the elements the primitive artist wishes to convey. Rimbaud was one of the early articulate people who listened to the inarticulate; Baudelaire, Shakespeare, and Homer formulated the states of mind of the people among whom they lived, and were able to penetrate states of mind which did not then exist – ours. Such persons find some method by which what they have to say is made available to those to whom they wish to say it. In the process of making it acceptable, what they have to say may be softened, made so tolerable and so bearable that its substance is lost to sight. Only the beauty of the work of art is seen: the *Odyssey, Iliad,* or *Aeneid* are mere poems. What lies behind the beautiful formulation,

drawing, painting, music, is lost; only the beauty remains. It appears almost accidental if something escapes from the prevalent force of the inhibitory authority. Instead of listening to music, someone listens to the radio interferences; there is a vast breakthrough of listening with more powerful instruments focusing on the interference; radio astronomy is born. Whether anybody wants to hear what they might hear thanks to increased powers of understanding, is an open question. The approach usually made by the combined wisdom of culture, the godlike omnipotence of the people, is to dismiss the newly discovered formulation as a construction – and then to erect a monument which it is hoped will be sufficiently weighty to keep the underlying corpse buried. The other procedure is equally efficacious – the deification or glorification of the person or thing disturbing the placid surface by saying, "Yes, you are a god just like us", and inviting the individual to join the Establishment. There are thus two means available to deal with the newborn idea or discovery, namely to bury it or to idealize it; to say the person is a genius – and therefore beyond us – or to say the person is crazy – and therefore beyond us. (The latter is safer locked in a mental hospital where the 'sanity' of the people cannot be penetrated.) Both mechanisms are discernible – but only at a distance. "These things happen – but not here. My colleagues and I don't behave like that." It is difficult to see that 'my colleagues and I' behave *just* like that. I can scrutinize myself as I am always available, whether awake of asleep; it is both difficult and unpleasant.

The escape from self-knowledge is easy and can be extremely violent – by self-murder. The group or society can, similarly, solve all its problems by killing another group or society or culture. These murderous impulses have so far not been adequate because the murderer is penetrated by the thing he murders, or the society is penetrated by the culture it is trying to destroy; the religion becomes impregnated with the religion whose place it is attempting to take.

On a quotation from Freud

1976

"There is much more continuity between intra-uterine life than the impressive caesura of the act of birth would have us believe." I don't know if I am misinterpreting this quotation, but I think it is not inappropriate that Freud says, "the impressive caesura . . . would have us believe", as if it were the caesura that governed us. This reminds me of the early Homeric description from which one gets the impression that the phrenes is really the origin of human thoughts and ideas – a very reasonable scientific conclusion because it is obvious that when a person expresses himself the diaphragm goes up and down. The diaphragm, the caesura, is the important thing; that is the source of the thinking.

Picasso painted a picture on a piece of glass so that it could be seen on both sides. I suggest that the same thing can be said of the caesura: it depends which way you look at it, which way you are travelling. Psychosomatic disorders, or soma-psychotic – take your choice – the picture should be recognizably the same whether you look at it from the psycho somatic position, or from the soma-psychotic position.

I want you to join me and try to achieve the same depths of ignorance I have managed to reach, to get back to a frame of mind which as nearly as possible is denuded of preconceptions, theories, and so forth. What I am asking is really something of a mental acrobatic feat. I can well appreciate that; it is not easy for people well versed in anatomy, physiology, psychoanalysis and psychiatry to get back to a state of primary ignorance.

I want to say something which sounds just like saying something for the sake of saying it; and perhaps it is. 'Bloody cunt'. 'Bloody vagina'. The first phrase is, I suspect, part of a universal language. It is not sexual; it is not physiological or anatomical, not medical; it is

something quite different. But 'bloody vagina' might be the sort of thing about which doctors talk, probably obstetricians or gynaecologists. What about the other one?

I am not going to try to produce the answer, not because I hope that the cure is ignorance, but temporarily, at any rate, I shall treat the answer as being a kind of disease of the question. (Doctor André Green once drew my attention to the quotation from Maurice Blanchot, "*La réponse est le malheur de la question.*") I want to draw attention to the sounds – bloody cunt. As I say, 'cunt' is not an anatomical or physiological phrase. What it is I don't know. Indeed, I throw it open to you, because if you investigate this question, you may find what this very primitive and archaic language is. 'Bloody' does not have much to do with the white cells, red cells, or whatever. It is, in fact, an abbreviated way of saying, 'By Our Lady'. So it is really part and parcel of what in more sophisticated terms we think of as being sacred.

This is very peculiar – 'cunt', and this sacred term mixed up with it. The sacred aspect of it would probably be much more meaningful to people familiar with the Roman Catholic religion. But I think one could find a similar sacred element without it necessarily having a Christian version. This is simply by way of introduction, to try to draw attention to the actual sounds of 'bloody cunt' and whatever its counterparts are. I do not, for example, know to what extent this phrase could be translated or recognized, shall we say, in Chinese or in Russian. The Chinese, at any rate, seem to be able to detect a difference in muscular movements of the face which are not the same among Russians as they are among themselves. The advantage of a conference of this kind is that so many different kinds of experience can be brought to bear on these matters.

The queer thing about this 'language' is that it seems to have an archaic quality which nourishes the more intellectual and less lively aspects of one's characteristic thinking, although without emerging to a point where one could verbalize it. A person, for example, who is very angry with somebody else might find that his intellectual and angry expression is nourished by these archaic factors which he cannot express but which do make the angry expression much more alive if he calls the other person a 'bloody cunt'. It will almost certainly lead to a great deal of turmoil of one kind or another.

Leonardo, in his *Notebooks,* has a great many drawings of water and hair. This seems to me to be an artistic delineation of this same

turmoil. When we disperse to the loneliness of our respective consulting rooms and offices, I suggest that what is there is turmoil. It may appear in a form revealed in verbal expression; it may appear in a form that would seem more appropriately called 'latency phase'. Palinurus is described, at the end of the fifth book of the *Aeneid*, as saying that Somnus must think he is very inexperienced if he can be led off course while steering his fleet on the calm and beautiful surface of the Mediterranean. This is something we should not forget; we should not be misled by the superficial and beautiful calm which pervades our various consulting rooms and institutions.

I would like now to indulge in some scientific fictions. I don't mean by that that I am not taking the problem seriously, but I know I shall never get anywhere nearer to a scientific statement. It seems to me that from a very early stage the relation between the germ-plasm and its environment operates. I don't see why it should not leave some kind of trace, even after the 'impressive caesura of birth'. After all, if anatomists can say that they detect a vestigial tail, if surgeons likewise can say that they detect tumours which derive from the branchial cleft, then why should there not be what we would call mental vestiges, or archaic elements, which are operative in a way that is alarming and disturbing because it breaks through the beautiful, calm surface we ordinarily think of as rational, sane behaviour?

A baby, quite satisfactorily born, cried and yelled at birth and could not be quieted; the more the mother soothed the child, the more it yelled. It became impossible for the mother to sleep because of this apparently indefatigable yelling. I suggest that this was a very late event in the story, hidden only because of the 'impressive caesura of birth'.

I don't suppose there will ever be any chance of knowing, so to speak, what a foetus thinks, but – to go on with my scientific fiction – I suggest that there is no reason why it shouldn't *feel*. I think it would be quite useful to consider that some stages of fear, of intense fear, are more easily visualized or imagined by us if we think of them as thalamic fear, or as some sort of glandular manifestation such as something to do with the adrenals, or what later on turn out to be the genital structures. You can look at this as you like, say as memory traces, but these same memory traces can also be considered as a shadow which the future casts before. I could say that this meeting

itself can be regarded as an expression, as a revision of such experience and knowledge as we have managed to pick up in the course of our lifetime, but it can also be regarded as showing the shadow of a future we don't know any more than we know the past, a shadow which it projects or casts before. The caesura that would have us believe; the future that would have us believe; or the past that would have us believe – it depends on which direction you are travelling in, and what you see.

It seems to me that there are certain premature and precocious developments that are too premature and too precocious to be tolerable. Therefore, the foetus, the id, does its best to sever that connection. At a later stage the individual can shut himself up. This happened with a man of thirty-odd years who drew the curtains of his room and as far as possible insulated himself from the universe in which he found himself. He objected to that universe, and at the beginning of the analysis objected to me sufficiently to bring his Smith & Wesson revolver to the sessions; he laid it ostentatiously by his side so as to have available the means of putting a stop to the interpretations. Luckily, or unluckily, having been an instructor in small arms, I paid a great deal of attention to that Smith & Wesson. It did rather distract me from paying attention to what the patient was saying, and I think the patient was similarly saved from having to pay too much attention to what I was saying.

Another patient was extremely sensitive to sight, so sensitive that it was difficult for him to wear ordinary clothes because their colours were intolerable. Another patient found it intolerable to listen to the Philharmonia Orchestra at a time when it was one of the supreme orchestras, because, according to him – and I believed him – the clarinettist played sharp; the problem then became how to shut it out.

A patient of this kind is very often intelligent, sometimes wise. I remember one poor wretch who had committed a murder, but his sentence was limited because it was discovered that he was of very low intelligence. Unfortunately for him, by the time he saw me, his intelligence was not low enough to be less than that required by the British Western Command which was anxious to punish him if he did not look after his rifle and bring it on parade. He said to me, "Sir, I am not fit to bear arms. I have been allowed out of gaol because they said I could be free if I would serve my country." Very difficult to do,

very difficult, especially if the country insists on giving him a lethal weapon which he knows he is not capable of carrying.

To continue with my science fiction, one cannot very well say this about a foetus, but I can imagine a situation in which, due to variations in pressure of the amniotic fluid, it could see light which might be intolerably bright, and hear sounds which might be intolerably loud. Is a foetus at full-term a character and personality, or not? When is that character or personality born? And when does that character or personality forget, get rid of, dispense with all that it has picked up in the course of existence in a liquid medium? In this liquid medium it seems to be possible, for certain animals at any rate, to achieve a kind of long-distance perception by being capable of smelling things; dogfish and mackerel congregate around some piece of decaying matter.

There appears to be quite an impressive change when this foetus changes to a gaseous medium, air, which is not liquid but is fluid. Therefore, once again there are oscillations and wave senses. I certainly do not see why there should not be a carry-over of extremely primitive sensitiveness; the foetus could be a healthy or sane object, and yet have been subjected to pressures communicated long before we would think there was such a thing as a personality, and long after it.

When I was a medical student, a small black cat used to appear at very regular hours in the forecourt of the hospital. It would 'do its stuff', cover it up neatly, and walk off. It was known as Melanie Klein – Melanie, because it was black; Klein, because it was little; and Melanie Klein, because it had no inhibitions. I have a feeling that this is repeated, as it were, on a rather different level of the heliacal progress of the human mind – borrowing from the molecular distribution of the DNA molecule. We come back to these same things, but on a somewhat different level. I think we are trying to get back onto the different levels without losing the vital contribution made by these archaisms.

Evidence

1976

The following free association was made to me by a patient in analysis. "I remember my parents being at the top of a Y-shaped stair and I was there at the bottom . . . and . . ." That was all; no further associations; finish. I waited, and during this time I, as usual, had plenty of free associations of my own (which I keep to myself because I am supposed to be the analyst). It occurred to me that this was very like a verbal description of a visual image, simply a Y-shape. The thing that struck me straight away about a statement that was so brief, so succinct, and stopped short at that point, was that it must have a lot of meaning that was not visible to me. What did in fact become visible to me I could describe by writing 'Y'. Then it occurred to me that it would be more comprehensible if it was spelled, 'why-shaped stare'. The only trouble was that I could not see how I could say this to the patient in a way which would have any meaning, nor could I produce any evidence whatsoever for it – excepting that this was the kind of image that it called up in my mind. So I said nothing. After a while the patient went on, and I started producing what seemed to me to be fairly plausible psychoanalytic interpretations.

Thinking about this later, I imagined a Y-shape which, when pushed in at the intersection of the three lines, would make a cone or a funnel. On the other hand, if it was pulled out at the intersection, then it would make a cone shape sticking out or, if you like, a breast shape. In fact it was an evocative free association on the part of the patient as far as I was concerned, but I was still lost because I had no idea of what I could say that would reveal an interpretation, and would also be comprehensible to the patient. In other words, could I possibly be perspicacious *and* perspicuous?

In the next session I seemed to be killing time with conventionally acceptable interpretations. Then I thought I would launch out on what I have been saying here. "I suggest that in addition to the ordinary meaning of what you have told me – and I am perfectly sure that what you said means exactly what you meant – it is also a kind of visual pun." And then I gave him the interpretation. He said, "Yes, that's right. But you've been a very long time about it."

Now the question is, what was the *evidence* that the patient was giving me, and what was the *evidence* that I saw, or thought I saw, for the interpretation? It is all very well for the patient to say, "Yes, that's right." I believe him. But I do not know why he thought it was right, or why it *was* right. In fact I don't know what the evidence is for that statement.

Freud, in his obituary notice of Charcot, lays great stress on, and obviously was enormously impressed by, Charcot's idea of going on staring at an unknown situation until a pattern begins to emerge and can then be interpreted. Charcot was, of course, talking about physical medicine, surgery and neurology. When it comes to psychoanalysis it is another matter; conventionally at any rate, we are not supposed to use our senses in physical contact with the patient. But we can attach enormous importance to the patient's presence – if he turns up. The problem, in a sense, is that of trying to make it worthwhile for the patient to come again another day. In theory there is no difficulty whatsoever; in practice it is very difficult indeed. So I think it is a matter of some congratulation if one retains the patient's curiosity or interest enough for him to come again.

There is still, however, this problem: what are we to say to people who are not psychoanalysts, or have not had psychoanalytic training, or, for that matter, if they have? So much of what we learn between the time we are born and the present is crudely perceptible through our senses; whatever else we learn is difficult to describe. Had I been able to verbalize it, I could have said what the evidence was for my supposing that this statement the patient made was a pun, but I still do not know what language to use if I am trying to communicate with somebody 'not me'.

Leaving that subject for a moment, I would remind you of Freud's statement, "There is much more continuity between intra-uterine life and earliest infancy that the impressive caesura of the act of birth would have us believe." He did not follow that up very far; on the

whole he seemed to dismiss it in the way that he says, "I learned to restrain my speculative tendencies and to follow the forgotten advice of my master Charcot, to look at the same things again and again until they themselves began to speak." That also seems to me to be very important; I have thought of it in terms of trying to dismiss memory and desire – memory as being a past tense; desire, a future tense. In other words, trying to start a session with as nearly blank a mind as one can get – which is not altogether very near because one has such an enormous past history between the time that one is born and the present day; such an extraordinary amount has been learned since becoming an inhabitant of a gaseous medium, the air. How much has been forgotten I do not know; indeed one of the revolutionary and disturbing theories in psychoanalysis is that it is questionable whether *anything* is forgotten in the sense of really disappearing. The important point about Melanie Klein's idea that at a very early stage the infant has a phantasy that it is able to split off what it does not like and evacuate it, is that it is an omnipotent *phantasy*; nothing happens, the situation remains unchanged, the personality remains unchanged. However, there is now an added layer of this phantastic belief that something has been got rid of. But suppose that it is not forgotten, that it simply becomes part and parcel of an archaic mentality, unconscious thought – in spite of the contradiction in terms – which is extremely active.

A surgeon is relatively lucky: he can say, "I think we could operate to relieve this pain that you are suffering in your back", because he has decided – although he doesn't say so – that the patient has a tumour in the form of a vestigial tail. Or, "Yes, we can operate on you." Again, he does not say why, but believes that the patient has a branchial cleft tumour. A surgeon would not be very popular if he behaved or talked as if he thought that the patient was a monkey or a fish or an amphibian. So it is not going to be popular if we psychoanalysts behave as if we think that the person of forty or fifty or sixty shows vestiges of states of mind that he thought he got rid of years ago. He prides himself on being grown up and on not believing that sort of psychoanalytic rubbish.

So we are back again to this same old problem: what are we to say? How are we to communicate to a patient? The surgeon can usually fall back on well-cared-for instruments that have been properly preserved and are already available in aseptic conditions. What we have

to use is articulate speech; the instruments with which we are to carry out *our* surgery are a sort of debased currency, words which are worn absolutely smooth till they are meaningless – terms like 'sex', 'fear', 'hostility' and so on. It is not surprising, therefore, that the patient thinks the analyst is talking the usual nonsense when we have to use words which are so debased – and which are pretty sure to get still more debased in the future. The alternative to that is to use technical terms, but that is just as bad because they are indistinguishable from jargon, just noises, 'learned' nonsense. For this reason I think that each analyst has to go through the discipline – which cannot be provided for him by any training course that I know of – of forging his own language and keeping the words that he uses in good working order. I do not think it has to be a particularly profound vocabulary, or particularly broad – it may be quite a narrow one – but it is very important that it should be the one that he chooses for himself. Nobody can tell you how you are to live your life, or how you are to think, or what language you are to speak. Therefore it is absolutely essential that the individual analyst should forge for himself the language which he knows, which he knows how to use, and the value of which he knows – knows so well that he can detect, when he gives an interpretation and the analysand repeats it with a slight change of intonation or emphasis, that although it sounds as if it is a repetition, in fact it is not. This is where the *practice* of analysis is so appallingly difficult: if you say nothing, you leave the patient to assume that he has correctly reported what you have just said to him; if you do draw his attention to the difference, you leave yourself open to the accusation that you are being pedantic and fussy, complaining about what he has said when he really repeated exactly what you said to him. You can point out, "You can't have repeated exactly what I said to you because this is about one and a half minutes later; time has been passing since I spoke to you, so what may *sound* just like what I said, in fact cannot be. You either understood what I meant – in which case there is nothing further to be said about the matter; either it was correct or it wasn't – or you are now saying something else."

If we attach so much importance to the caesura of birth, then we have to consider what language the full-term foetus speaks or understands. We are not so far called upon to analyse full-term foetuses, but we *are* expected to analyse grown-up children. People come to us, probably through despair because they do not in fact think that

much can be done for them, but they are in a state of turmoil. This state of turmoil is well illustrated by Leonardo in his drawings of hair and turbulent water, but it is not really made clear by him, nor even by Shakespeare. I think it *is* made clear by Francis Bacon who wrote, in *Novum Organum,* "There are two ways, and can only be two, of seeking and finding truth. The one, from senses and particulars, takes a flight to the most general axioms, and from these principles and their truths, settled once for all, invents and judges of intermediate axioms. The other method collects axioms from senses and particulars, ascending continuously and by degrees, so that in the end it arrives at the more general axioms; this latter way is the true one, but hitherto untried." To exaggerate the difference between Leonardo, Shakespeare and other artists, and what Francis Bacon is driving at in his statement here, I could resort to Kant's statement, "Intuitions without concepts are blind; concepts without intuition are empty."

Our problem is, how are we to introduce the intuitions to the concepts, and the concepts to the intuitions? Putting it another way, how are we to state, in conscious rational speech, something which can be recognizably married to a feeling? I sometimes think that a feeling is one of the few things which analysts have the luxury of being able to regard as a fact. If patients are feeling angry, or frightened, or sexual, or whatever it is, at least we can suppose that this is a fact; but when they embark on theories or hearsay we cannot distinguish fact from fiction. Or, as Freud put it, individuals suffer from amnesias, and then invent more paramnesias to fill the gaps. It would be so nice if it were only patients who did it. And so fortunate if *we* did not. It is just as well to bear in mind the possibility that we, as psychoanalysts, are dealing with a most extra-ordinary thing – a personality, a character. You cannot touch it, smell it, or feel it, and if you are at all tired and more than usually ignorant, it is useful to reach out for the nearest paramnesia that is handy, the nearest psychoanalytic theory that you find lying around. What if the whole of psychoanalysis turned out to be one vast elaboration of a paramnesia, something intended to fill the gap – the gap of our frightful ignorance?

To resort to yet another pictorial image, the comment by Beachcomber [J. B. Morton] on the Ship of State – and I must say it was a very eminent statesman indeed [Winston Churchill] who talked about "Sailing on the Ship of State". "It just shows that, whatever else may be wrong with the Ship of State, there is nothing wrong with the

bilge." In short, there is an inexhaustible fund of ignorance to draw upon – it is about all we do have to draw upon. But let us hope that such a thing as a mind, a personality, a character exists, and that we are not just talking about nothing. I must confess that I do feel, partly I suppose because of my prejudice, that in analysis we are dealing with *something*, something that is very difficult to describe. The artists have a great advantage because they can resort to the aesthetic as a universal linguistic. The defects of verbal communication were clearly discerned about two thousand years ago by Plato: in the *Phaedo*, describing the trial of Socrates, he points out what a great disadvantage it is that in spite of the fact that Socrates and Phaedrus can apparently talk very accurately and precisely, they are actually using extremely ambiguous terms. I do not see that we have made much progress in that regard in the last two thousand years.

If we consider that there is a thing called a mind or a character, is there any way in which we can verbalize it which is not a complete distortion? The mathematicians talk about 'quantum intermediacy', something unknown in between; we can imagine some sort of screen onto which these various elements project themselves. For example, Picasso paints a picture on a sheet of glass so that it can be seen from either side. Using my hand, I suggest something of this sort: look at it from one side; there is a psychosomatic complaint; turn it round; now it is soma-psychotic. It is the same hand, but what you see depends on which way you look at it, from what position, from what vertex – any term you like. But does one look at a character from any direction at all? I cannot see how this problem is to be solved except in the practice of analysis, and except by the particular analyst. It is no good anyone trying to tell you how you look at things, or from where you look at things – no one will ever know except you.

Let us take flight into fantasy, a kind of infancy of our own thought. I can imagine a situation in which a nearly full-term foetus could be aware of extremely unpleasant oscillations in the amniotic fluid medium before transferring to a gaseous medium – in other words, getting born. I can imagine that there is some disturbance going on – the parents on bad terms, or something of that sort. I can further imagine loud noises being made between the mother and the father – or even loud noises made by the digestive system inside the mother. Suppose this foetus is also aware of the pressures of what will one day turn into a character or a personality, aware of things like

fear, hate, crude emotions of that sort. Then the foetus might omnipotently turn in hostility towards these disturbing feelings, proto-ideas, proto-feelings, at a very early stage, and split them up, destroy them, fragment them, and try to evacuate them. Suppose this caesura takes place and the infant is subjected to the trauma of birth, and the further trauma of having to adjust to a gaseous medium. I can imagine the foetus being so precocious, so premature that it tries to get rid of its personality to start off with, and then after birth – still being highly 'intelligent', if that is the correct term – is able to learn all the words and phrases which people consciously use. In the very severe, very obtrusive situation such as the one I have in mind, that person learns well the difference between right and wrong; the M'Naghten Rules (the governing decision as to criminal responsibility of the insane) present no difficulty whatever. But as far as he is concerned he may preserve a mind at the deeper level which knows nothing about that, but which might nevertheless have well-established feelings of guilt. I have been amazed to see the way in which, if you make a faintly disapproving sound to a baby, it will wince as if it had been subjected to an almost intolerable accusation. Has the baby a kind of well-established 'conscience'? What is one to call it? I have invented terms for my own private purposes like, 'sub-thalamic fear', meaning the kind of fear that one would have if no check on it at all was produced by the higher levels of the mind. A patient may in fact be subject to tremendous feelings of fear. I remember one who was quite articulate, in fact articulate enough to make me think that I was analysing him rather well. Indeed the analysis did go extremely well, but I was beginning to think that nothing was happening. However, the patient checked all that. After a session he went home, sealed up all the crevices throughout his room, turned on the gas, and perished. So there was my highly successful analysis – a very disconcerting result indeed, and no way of finding out or learning for myself what exactly had gone wrong, excepting the fact that it had undoubtedly gone wrong.

Supposing we are in fact always dealing with some kind of psychosomatic condition. Is it any good talking to a highly articulate person in highly articulate terms? Is it possible that, if feelings of intense fear, self-hatred, can seep up into a state of mind in which they can be translated into action, the reverse is true? Is it possible to talk

to the soma in such a way that the psychosis is able to understand, or vice versa?

It would be useful if we could formulate our own impressions about this before giving them an airing. It is important to recognize that there is a world in which it is impossible to see what a psychoanalyst can see, although it may be possible for some of those who come for analysis to realize that we see certain things which the rest of the world doesn't see. We are investigating the unknown which may not oblige us by conforming to behaviour within the grasp of our feeble mentalities, our feeble capacities for rational thought. We may be dealing with things which are so slight as to be virtually imperceptible, but which are so real that they could destroy us almost without our being aware of it. *That* is the kind of area into which we have to penetrate.

Making the best of a bad job

1979

When two personalities meet, an emotional storm is created. If they make sufficient contact to be aware of each other, or even sufficient to be *un*aware of each other, an emotional state is produced by the conjunction of these two individuals, and the resulting disturbance is hardly likely to be regarded as necessarily an improvement on the state of affairs had they never met at all. But since they *have* met, and since this emotional storm has occurred, the two parties to this storm may decide to 'make the best of a bad job'.

In analysis, the patient comes into contact with the analyst by coming to the consulting room and engaging in what he thinks is a conversation which he hopes to benefit by in some way. Likewise the analyst probably expects some benefit to occur – to both parties. The patient or the analyst says something. It is curious that this has an effect; it disturbs the relationship between the two people. This would also be true if nothing was said, if they remained silent. I often do remain silent, hoping to see, or become aware of, or observe something which I could then attempt to interpret – I usually leave the initiative to the patient if I can. The result of remaining silent, or of intervening with a remark, or of even saying, "Good morning", or, "Good evening", sets up what appears to me to be an emotional storm. One does not immediately know what the emotional storm is, but the problem is how to make the best of it, how to turn the adverse circumstance – as I choose to call it at the moment – to good account. The patient is not obliged to do that; he may not be willing or able to turn it to good account; his aim may be quite different. I can recall an experience in which a patient was anxious that I should conform to his state of mind, a state of mind to which I did not want to conform. He was anxious to arouse powerful emotions in me so

that I would feel angry, frustrated, disappointed, so that I would not be able to think clearly. I therefore had to choose between 'appearing' to be a benevolent person, or 'appearing' to remain calm and clear-thinking. But acting a part is incompatible with being sincere. In such a situation the analyst is attempting to bring to bear a state of mind, and indeed an inspiration, of a kind that would in his opinion be beneficial and an improvement on the patient's existing state of mind. That interference can be resented by the patient whose retort can be to arouse powerful feelings in the analyst and to make it difficult for the analyst to think clearly.

In war the enemy's object is so to terrify you that you cannot think clearly, while your object is to continue to think clearly no matter how adverse or frightening the situation. The underlying idea is that thinking clearly is more conducive to being aware of 'reality', to assessing properly what is real. But being aware of reality may involve being aware of the unpleasant because reality is not necessarily pleasing or welcome. This is common to all scientific inquiry, whether of people or things. We can be in a universe of thought, a culture, or even a temporary culture, of such a kind that we are sure to suffer the pain of feeling that our universe is not conducive to our welfare. To dare to be aware of the facts of the universe in which we are existing calls for courage. That universe may not be pleasing and we may be disposed to get out of it; if we cannot get out of it, if for some reason our musculature is not working, or if it is not appropriate to run away or to retire, then we can be reduced to other forms of escape – like going to sleep, or becoming unconscious of the universe of which we do not wish to be conscious, or being ignorant, or idealizing. 'Escape' is a fundamental cure; it is basic. The infant, unwilling to be aware of its helplessness, ideal-izes or ignores. (I use 'ignores' as the process requisite to reaching 'ignorance'.) It also resorts to omnipotence; thus omnipotence and helplessness are inseparably associated. The tendency is to objectify omnipotence in the person of father or mother, or god or goddess. Sometimes it is made easier by a physical inheritance such as good looks: Helen of Troy could mobilize great powers through her beauty, as we know through Homer – "Is this the face that launched a thousand ships and burned the topless towers of Ilium?" Much the same thing can apply to the male who can be fortunate enough to be Paris or Ganymede, whose ability to achieve omnipotence was facilitated by their physical legacy, their

physical capital. The body can be brought in to redress the unpleasure of the mind; reciprocally, the mind can be brought in to redress the unpleasure of the body. The basic assumption of psychoanalysis is that the 'function' of the mind can be used to correct the fallacious solutions which I have briefly sketched. But sometimes a cosmetic power is not enough; the solution to which such a person has been tempted has not in fact been robust enough or durable enough to meet the further exigencies of existence. For example, if a soldier is given authority by virtue of his physical appearance, the facts of waging war may impose a burden on cosmetic beauty that it cannot carry.

I would make a distinction between existence – the capacity to exist – and the ambition or aspiration to have an existence which is worth having – the quality of the existence, not the quantity; not the length of one's life, but the quality of that life. There are no scales by which we can weigh quality against quantity, but existence is to be contrasted with the *essence* of existence. The fact that the patient, like the analyst, is still in existence is not adequate; this inadequacy is inseparable from the drive responsible for the existence of the two people, analyst and analysand, in the same room at the same time.

This paper I claim to be scientific, but I do not think you are likely to agree that it merits being so categorized, for I shall continue with a series of statements for which I have not a shred of factual support. They are these: the Self that the psychoanalyst observes – the analyst having the same characteristics – has, according to the embryologists, some growing objects which they call the cortex and medulla of the adrenals. Those names are given to these structures as soon as they assume a pattern that is observed in different individuals at different times and dates. These bodies in course of time become functional and produce a chemical substance which is concerned with aggression, or fighting, or flight. I prefer to be less precise and to exclude any element of direction by saying that the adrenals do not provoke fight or flight, but provoke 'initiative'. The terms that I use – fight, flight, initiation – would be appropriate if the object being observed had a psyche. To get over the difficulty, the obstacle to progress that is presented by my lack of intelligence or knowledge, I shall resort to imaginative conjectures in contrast to what I would call *facts.* The first and most immediate of these imaginative conjectures is that the adrenal bodies do not think, but that the surrounding structures develop physically and in physical anticipation of fulfilling a function

we know as thinking and feeling. The embryo (or its optic pits, auditory pits, adrenals) does not think, see, hear, fight, or run away, but the physical body develops *in anticipation* of having to provide the apparatus for filling the functions of thinking, seeing, hearing, running away, and so on. Since I cannot *know* – and am most unlikely to have the necessary intelligence in the course of my ephemeral existence – I try to convey to the body politic these gropings towards intelligence in case my own anticipations lead to the contagious and infectious communication of these conjectures which may in due course become real-ized.

So far I am only discussing the physical body as if it anticipated functions which would later on come to pass, but which would already have a bodily equipment suitable for serving the purposes of a particular function that we call 'psyche'. This is what I name a 'physical anticipation', a bodily anticipation making possible the later *functional* operation of a mind. I am borrowing from psychology in order to describe a physical matter; later I borrow from a physical matter to describe something psychological.

I now turn to the problem of communication within the Self. (I dislike terms that imply 'the body' and 'the mind', therefore I use 'self' to include what I call body or mind, and 'a mental space' for further ideas which may be developed. The philosophical statement of this approach is Monism.) When we are engaged on psychoanalysis in which observation must play an extremely important part – as has always been recognized in a scientific inquiry – we should not be restricting our observation to too narrow a sphere. What then are we observing? The best answer that I know is provided by the formulation in Milton's introduction to the Third Book of *Paradise Lost.*

> So much the rather thou Celestial light
> Shine inward, and the mind through all her powers
> Irradiate, there plant eyes, all mist from thence
> Purge and disperse, that I may see and tell
> Of things invisible to mortal sight.

When the patient comes into the consulting room the analyst needs to be sensitive to the totality of that person; it should, for example, be possible to see a flush on the face as a physical manifestation of the blood system, as well as being able to hear the words which that person utters as a part of the operation of the vocal musculature – not

particularly emphasizing the activity of the voluntary muscles, nor yet particularly the sounds which are created by the vocal cords and the vocal apparatus, but rather the *total* thing. As Donne wrote in *The Second Anniversary:*

> Her pure and eloquent blood
> Spoke in her cheeks, and so distinctly wrought,
> That one might almost say, her body thought.

Or, putting it differently, the analyst needs to be able to listen not only to the words but also to the music, so that he can hear a remark which is not easily translated into black marks on paper, which has a different meaning when it is made in tones of sarcasm, or in terms of affection or understanding, or by a person who has actual experience of authority – though the words might be the same in each instance. For example, it might be possible to think in terms of an ideal world, a Utopia, as Sir Thomas More did, and to write it in terms which can still be understood by those who care to read his book. In the analytic session there is a difference when words are spoken by an analysand who is a man of authority, accustomed to wielding authority. When he talks about some ideal constitution, what he has to say will be different from the same words said by a person who has no such power and no such authority.

What I am saying may appear to be painfully obvious. My justification for saying it is that the obvious is so often not observed, namely, that which is the *difference.* So I think that it is worth while mentioning these obvious facts – otherwise they will not become the object of scrutiny on which any kind of scientific progress depends. When I say 'scientific' in this context, I mean the process of realization as contrasted with the process at the other 'pole' of the same concept, ideal-ization, the feeling that the world, the thing, the person, is not adequate unless we alter our perception of that person or thing by idealizing it. Real-ization is doing the same thing when we feel that the ideal picture which we present by our statement is inadequate. So we must consider what is the method of communication of Self with Self.

A great deal of work has been done in studying the central nervous system, the para-sympathetic and the peripheral nervous apparatus. But we have not considered the part that is played, if any, in the communication of thought, or the anticipation of thought by the

glandular system. As tuberculosis of the lung can be communicated, say, with the lymphatics of the lower limbs, so perhaps the thoughts which we are accustomed to associate with the cerebral spheres could likewise be communicated to the sympathetic or para-sympathetic, and vice versa. Such a conjecture could account for the peculiar state of affairs when a patient says that he is terrified or is very anxious, and has not the slightest idea what about. We are familiar with using free associations for purposes of interpretation; I wonder whether it is also possible to use or to tap these communications before they reach the cerebral spheres, before they reach the area which we regard as conscious or rational thought. Can any part be played in all this by what I have called 'imaginative conjectures'? I would also add 'rational conjectures'; that is to say conjectures which seem to be linked with reasonable activity or the activity which has a ratio. Compare this kind of thought with that which communicates itself in tossing and turning in bed when we are asleep and are having what we describe as a 'restless night', or with the patient who talks about having catarrh or rhinitis. Anatomists call a part of the brain the 'rhin-encephalon' – as if they think there is such a thing as a nose–brain. I understand from the embryologists and physiologists that the sense of smell is a distant receptor in a watery fluid – sharks and mackerel provide a model of that long-distance receptor. But the human being has to carry some of this intra-cellular fluid into the world after birth where the fluid is not watery but gaseous. The watery fluid, instead of being an asset, can become a liability; the individual can complain of rhinitis and difficulty in breathing. Or a patient may complain of an inability to stop the flow of tears – another excretion of fluid which has its uses; it can irrigate the eyeball and wash away dust and dirt, but an excess blinds the patient with tears.

At the risk of being monotonous on the one hand, and on the other of appearing to be changing the subject, I propose now to repeat the essence of what I have been saying. Suppose we regard being asleep as being in a particular state of mind in which we see sights, visit places, and carry out activities which are not usually carried out by us when we are awake – although there can be activities which we carry out when we are awake which are reminiscent of dreams; people say that they go to a place to which they have always 'dreamt' of going, speaking metaphorically. The change from the state of mind in which we are when asleep (S-state) to that in which we are when

awake (W-state) is reminiscent of the change from watery fluid to gaseous fluid, pre-natal to post-natal. We have a prejudice in favour of the W-state: people, without hesitation, talk about having had a dream, often meaning that therefore it did not really happen. But I would say that that is a prejudice of a person who is in favour of the voluntary musculature, who does not attach importance to where he can go unless he can do it by the use of his voluntary muscles. We do not hear much about the places we visit, the sights we see, the stories we hear and the information which is available when we are asleep – unless we translate it into being awake.

Who or what decides the priority of the W-state over the S-state? My question may appear to be somewhat ridiculous. But I shall exaggerate it by changing its form and saying: who or what decides the state of mind of a man who says, as reported by Hanna Segal, that anybody would recognize that the person playing the violin is really masturbating in public? That is a point of view; it is clear enough; there is not much doubt about its expression. Why is it that we take it for granted that a person is really playing the solo part in the Brahms violin concerto and that this view is the correct one, superior to the view of the person who knows that the soloist is in fact masturbating in public? From that vertex, can the psychotic patient put up a claim when opposed by the view of the 'sane'? Would it be possible for a psychotic to say, "Poor fellow – he thinks it is the Brahms violin concerto – a typically sane point of view. Quite wrong of course, but he is unfortunately sane"? This point is more obscure when I say that the W-state, and the story about what we did when asleep, is as depicted when wide awake. What of the psychoanalyst who thinks that the account of the story told by a person who is awake deserves interpretation in order to reveal a meaning other than the perfectly simple, straightforward account of the events if they are considered to be factual descriptions of factual events? After all, what is wrong with the factual event when the person is asleep? In what way is this the incorrect view? In what way should we throw our votes in the scale? For the W-state, when we have subjected the experience that we have when asleep to wake-work? Or for translating, according to psychoanalytic theory, the events of the day or the events of conscious thinking, into some other form of thinking which is done by the process of dream-work? In other words, what about the process done by the wake-work to translate the events, the places we have been,

the sights we have seen when asleep, into the language of a person who is awake? What work would be necessary to translate the state of mind of the person who sees that the violinist is masturbating in public into the terms used by the people who think it is a Brahms violin concerto? Is that work reasonably called a 'curative' activity? Certainly any work which was done to translate the state of mind of the person who thinks that it is a Brahms violin concerto into a state of mind of the person who thinks that the individual concerned is masturbating in public would not be considered to be a cure; on the whole the majority vote would seem to be in favour of the view that such a person had deteriorated, had suffered a misfortune as a result of his analytic experience.

If the S-state is regarded as being worthy of respect equally with the W-state – the arbitrium being impartial – then where one went, what one saw and experienced, must be regarded as having a value which is equally valid. This is implicit when Freud, like many predecessors, regards dreams as worthy of respect. So we can say that the wake-work should be considered as equally worthy of respect as is the dream-work. But why is the state of mind of being awake, conscious, logical, regarded as having 'our wits about us', but only if it is *half* our wits? How awful when you find a maggot in your apple! Not so awful as finding half a maggot in your apple. So we find that only having half our wits about us is a discovery that is most disturbing. It is one reason why there is a division of opinion as to whether to have *all* our wits about us, or to get back to having only one half – the wakeful, conscious, rational, logical. Only that kind of mathematics that is generally accepted by the majority, the prevalent culture, the social, civil, dominant fashion, is regarded as valid.

Suppose we respect equally both states of mind, or many states of mind whatever they are: then what state of mind shall we choose for interpretation? Verbal action? That is an everyday problem. In our present culture it is not thought correct to make a rhapsodic response, an immediate abandonment of the screen between impulse and action, translating the impulse direct into action without any intervening delay. It is considered to be equally incorrect to prolong thought to the point at which the action is so delayed that it either does not take place at all, or thinking becomes a substitute for action. When virtually instantaneous action is called for, it is likely to precipitate a response that is rhapsodic, impulse direct to action without any

intervention of thought. Freud described Two Principles of Mental Functioning; I suggest Three Principles of Living. First, feeling; second, anticipatory thinking; third, feeling plus thinking plus Thinking. The latter is synonymous with prudence or foresight → action.

A man has much muscular activity: when awake, he says he has had a restless night. Where did he go? What did he see? Who was he? What did he do? Should the W-state prevail and be accorded superiority? Should he respect the state of mind which was associated with so much physical activity? What is certain is that that physical activity which the patient has experienced is unmistakable whether he or his analyst recognizes it; he often admits, unwillingly, that he is tired.

Perhaps the problem can be approached more easily by projection. Let us consider it not in each one of us individually, but by regarding it as a problem of the body politic. Can we then locate in the community the origin, the source, the emotional storm centre? In my experience it is always caused, or associated with, or centred on a thinking and feeling person who can make his Self infectious or contagious. To take a gross example, Shakespeare; it is said that the English language has never been the same since. I have asked why we go to hear scientific papers. If you want to be reminded of people and the way they behave, do you choose a Shakespeare play, or do you come to an alleged 'scientific' paper by me? I will not embarrass you or myself by pressing such a question, especially as I do not have to pronounce a solution to that problem. It does, however, have a long history extending to periods before Shakespeare, or indeed before modern English existed. It appears to have agitated the Arians, though they were mostly concerned with the problems of material existence and conquest. I do not think it is oversimplifying to say that even from the earliest periods of human history of which we have any record – the Rig Veda – there appears to have been a need to develop what we now call a 'philosophy of thinking'. But a philosophical discussion about the ancient wisdom of the Rig Veda and the other Vedanta (ancient Hindu scriptures) became tainted with hostility, as did the philosophy of the Greeks in the time of Plato and Socrates.

> *Socrates*: My art of midwifery is in general like theirs; the only difference is that my patients are men, not women, and my concern is not with the body but with the soul that is in travail of birth. And the highest point of my art is the power to prove by every test whether the offspring of a young man's thought is a

> false phantom or instinct with life and truth. I am so far like the midwife that I cannot myself give birth to wisdom, and the common reproach is true, that, though I question others, I can myself bring nothing to light because there is no wisdom in me. [Plato, *Dialogues – Theaetetus*.]

It became so feared and disliked by the authorities that the Emperor Justinian closed the philosophical schools. But he was too late: a germ of philosophical thinking escaped to Edessa in Babylonia and was again suppressed. But then, owing to the spread of Christianity by virtue of the employment of the Greek language, the language of the philosophers began to be studied again as an incidental offshoot of the study of Christianity. To cut a long story short, it was again locked up in Byzantium until the fall of the Byzantine Empire and Constantinople. These lost wisdoms were then released and broke out to create the virulent emotional turmoil that we know as the Renaissance. Wisdom seems to have this capacity for survival by changing its route and then reappearing in unexpected places.

> Return Alpheus, the dread voice is past,
> That shrunk thy streams; Return Sicilian Muse . . .
>
> [Milton, *Lycidas*]

Galen established the rights of observation and became authorized, respectable – just as Freud is today – and an authority with which to suppress inquiry. Anatomy was not then studied by looking at the human body, but Leonardo, Raphael and Rubens studied the body, and as a result of this emergence amongst the artists, the anatomists too began to observe the cadaver, physiologists to study the mind.

Will psychoanalysts study the living mind? Or is the authority of Freud to be used as a deterrent, a barrier to studying people? The revolutionary becomes respectable – a barrier against revolution. The invasion of the animal by a germ or 'anticipation' of a means of accurate thinking, is resented by the feelings already in possession. That war has not ceased yet.

INTERVIEW BY
ANTHONY G. BANET, JR.
1976

‘Interview by Anthony G. Banet, Jr.’, first appeared in 1976 in *Group & Organization Studies, 1* (No. 3, September, pp. 268–285), published by University Associates Inc. It was subsequently published in 2005 as Appendix B to *The Tavistock Seminars,* edited by Francesca Bion (London: Karnac Books).

Interview by Anthony G. Banet, Jr.

Los Angeles, 3 April 1976

Banet: In *Experiences in Groups*, you allude to your wartime experiences. I'd like to hear more about that.

Bion: During the First World War, I went straight from school into the army and into the tanks because I wanted to see what a tank was. At that time they were still secret. I spent the rest of my time regretting it. It's very difficult to talk about the regret.

The military is a most peculiar business, because you are with a person only briefly, but you find that you get to know him quickly, very well, and in depth. There's nothing like this business of constantly being confronted with the probability of death. We had something like 700 officers come through our battalion in the short space of time in which we were in action – just about eighteen months. The result is that I knew individuals very, very well, but I would forget their names because I saw them so briefly. I remember coming across a fellow who wasn't in my company, but he recognized me. He was an AA scout – one of these people who go about on motorcycles. I recognized his face when he introduced himself to me, but I could not place him. But that's the kind of thing that helped me to see that I really felt extremely deeply about the people I knew.

Banet: It sounds like a very stressful time. Did these experiences contribute to your theoretical formulations about groups?

Bion: No, not really, but I suppose they had some influence. It is such a hard thing to describe. In my first combat action, I had the intense feeling that I must not get frightened – I must not run away. (Of course, you can't run away – it's impossible – you discover that.)

Another thing that you discover is that you don't settle anything in combat. You become more and more frightened, because you get to know more and more what the dangers are. That, I think, was a very unpleasant discovery. Mind you, I think that a good soldier, a regular soldier, can learn a very great deal. He doesn't become less frightened, but he knows how to look after himself.

Banet: The fear never leaves you.

Bion: Never.

Banet: Were you practising medicine or psychiatry at that time?

Bion: No, that came later. I was simply a combatant soldier. The curious thing was the great relief I felt when it was over, and then the discovery that, in fact, it had left very deep marks indeed.

I went straight up to Oxford after the war, and it was marvellous. Everything at the university was so exciting and so interesting, but it simply made it impossible to work out anything that had been simmering inside me. When I was at Oxford, there were a lot of tragedies of ex-service personnel. Another thing – the college authorities were surprised to find that virtually all officers were extremely well disciplined. There was no trouble whatsoever. A lot of people had expected a return of the "licentious soldier". We were seduced into a belief that everything was beautiful – as indeed it was. But it was very hard to realize why, while everything was so magnificent, we did not feel the privilege of enjoying it. Always, there was just a shadow of some kind – a frightful thing that never really left our minds. We simply attached it to new tasks like getting through finals, but I'm certain that the shadow of war was a background for all of us.

Banet: But the shadow was not talked about.

Bion: Not talked about, no. Evelyn Waugh described it, rather to my surprise, I must say, when he said what a relief it was to get rid of our whole crowd, because we simply put a damper on the whole university. The university was overshadowed, from his point of view, by the ex-servicemen and the war people who were a dead weight. You couldn't make progress; you couldn't get through this "crust". Of course, he was sitting on top of the university. From our own point of view, we rather resented the "kids", so to speak, who had no war service and who thought they were the big noises of the university. But that didn't matter, of course, because we had so much more

experience. I think that the university did suffer from having this great mass of ex-service people there.

There was the attempt to be very nice to the ex-servicemen, but the others didn't know what our problems were. All they could do was to give us comfortable rooms, good food and all of the creature comforts. From the point of view of the university authorities, there was very little that they could do about us. We were very pleased to plunge ourselves into all the diverse activities that existed. I was fortunate because I was a pretty good athlete. I was captain of the Oxford University Swimming Club. So I had plenty to occupy myself. I also played rugby for the university. I'm not sure whether it was really lucky or not, because it enabled us to cover over the terror, and we fell in with this idea that everything was so marvellous – as it was.

Banet: It was easy to forget the terror . . .

Bion: Yes . . . we just forgot it. A friend of mine went down to Manchester, and when he returned he said, "You know, the university is like a nightmare in reverse. You have no conception whatsoever of the state of affairs in Manchester: the misery, the unemployment, the total conditions. I walk in here – the rowing, the excitement, the races – and it's like coming into an utterly and totally unreal world of happiness, pleasantness, comfort – whereas when we go to Manchester we walk straight into this frightful state, which is actually the real one."

Banet: Margaret Rioch, in one of her comments on the Tavistock model,[1] points out its strong emphasis on the tragic aspects, the seriousness of life. Your story sounds like the same thing – that behind all this idyllic university scene you were being reminded by your friend that there were serious conditions in Manchester – world events that were causing people pain.

Bion: I don't think it is very unusual that one covers pain over with something that isn't tragic. If it's a nice day, you're jolly thankful it's a nice day; if I think back about England now, I always think of the weather as sunny. You just forget those vast spaces of time in which the fields are under water and that the springtime is cold and miserable and beastly. All you remember are the summer days – the

[1][Margaret Rioch was the founder in 1969 of the A. K. Rice Institute, which developed along group relations lines as the U.S. counterpart of the Tavistock Institute. *Ed.*].

summer weather and the summer conditions. You tend to concentrate on how magnificent everything is – how good life is – and to resent anybody who reminds you that, for most people, it isn't. Of course, nearly everybody learns the same trick – pretending to be more happy or fortunate than he actually is. Then you are taken by surprise if you happen to be taken ill. The illness itself is treated as if it were a fluke. I think that the more correct statement would be that the health of the individual is a fluke. For some reason, we've got this kind of apparatus up here in our heads which enables us to believe that good health – the kind of health you have at age thirty – is normal.

Banet: That viewpoint seems very much opposed to the human potential movement – the celebration of individuality, the talk about joy, about community. I'd be interested in how you view contemporary group movements that emphasize fulfilment and happiness.

Bion: I don't really know enough about any of these other movements to be able to say anything particularly knowledgeable about them, but I do know about psychoanalysis. Psychoanalysis is based on the premise that it is abnormal to be unhappy – to be anxious – but it seems to me that as one goes into the business of dealing with others, it's a very questionable premise indeed. The usual part of life is involved with tragedy, sadness and decaying health. After all, one's health decays from the moment of birth, and there are people who have never been well; in some ways I think that they could be saner than people like myself who've had good health and who have been good athletes. A healthy person just doesn't appreciate why on earth he should have anything else but health. I don't know how to rate the baselines, but perhaps we should consider that suffering and rivalries with other human beings are really the normal standard. The poor, those who are less well-off, or the unhappy would naturally covet the riches, the wealth and the comfort of those who are well-off. This would apply to nations just as much as to individuals. It might be quite reasonable to suppose that the natural thing would be for wealthy and successful nations or individuals to find that they are the target of hostility.

Banet: It was, I think, Melanie Klein who stimulated your interest in psychoanalysis.

Bion: Yes, Melanie Klein has certainly influenced me. Before that,

John Rickman, whom I liked very much, was also very influential, although it was clear later on that he had various personal difficulties. We have to use people who have these difficulties. They are the people who become our teachers; they are the people who make the advances. I certainly remember him with a great deal of affection.

Banet: Was he at the Tavistock Institute?

Bion: No. He was at the Institute of Psychoanalysis, but he was one of these "heretics" who had dealings with the Tavistock Institute, which was really considered to be grossly improper by the psychoanalysts.

Banet: Were you a heretic, too, at the Tavistock?

Bion: Yes, I was. But I was also a heretic in the other direction because, although a member of the Tavistock Institute, I made contact with psychoanalysis and wanted to be, and did become, a psychoanalyst. In those days the British Institute of Psychoanalysis was afraid of appearing to condone activities that were not psychoanalytic by cooperating with the Tavistock Institute. It is not unlike the situation in the United States when American psychoanalysts think that psychoanalysis will be undermined by sanctioning psychoanalysts who support the theories of Melanie Klein.

I think the Tavistock Institute was then afraid that the freedom of thought, supposed to be the hallmark of the Institute, would be endangered by the bigotry and rigidity of the psychoanalysts. Therefore, any interchange between Rickman and members of the Tavistock was regarded with suspicion by both parties.

Banet: A. K. Rice is often regarded as a primary pupil of yours. Do you see him extending the theory?

Bion: I don't really know enough of what he did. I was present with him only once at Amherst, when he took a small group (he didn't take the whole group), so I didn't really have a chance to get up to date with what he was doing. He happened also to be very ill, although I didn't know it at the time.

Banet: Your group theory emphasizes that a basic assumption of life exists below the surface of the group's work life. I'd like to hear your comments on how this operates in groups.

Bion: Both words – basic and assumption – are important. It seems

to me that it is not simply the assumption that is basic, but also that the thing that one's trying to talk about is basic. The difficulty is to know how to define or to detect this basic theory. You try to talk in as polite and civilized a manner as possible, but in the secrecy of your own mind, if you think of it, you're awakened by reality as you are jolted awake by an alarm clock. What language do you use about your alarm clock? How does language connect the basic, secret fantasy aspects of your mind with the realities of the outside world?

In groups, you have the opportunity to hear language that attempts to express these basic assumptions. Indeed, one of the points about groups is that they provide an opportunity to see things collectively. Instead of a line of thirty people, one after the other, you see the whole collection of thirty people together. I think the group is a distortion, but so is a survey map – where you portray mountains and valleys on a flat surface by using contour lines. The group approach ought to have its own methods of portraying its basic assumption of life. What that method is, is yet to be discovered, but it needs to be something that jams a whole lot of data together to portray the results on a flat surface.

Banet: Many people regard the notion of "basic assumptions" in groups as the key to understanding group process. But you're saying that the method to use that key needs to be elaborated.

Bion: Yes, I think the notion of "basic assumption" needs tremendous investigation. For example, we all know people with rheumatic pains. An ordinary general practitioner in England knows of people who have been bedridden twenty or thirty years. Cancer gets all the publicity because nobody can be bothered with a subject like rheumatic complaints that is boring and tiresome and won't go away. I think that this is the direction in which the investigation of groups could go. If you could persuade thirty people with rheumatic pains to meet together, you would learn something. You would have to have a group expert, because I don't think that you could possibly keep a collection of people like that together – they would hate each other so much. They'd dare to come once, but then they would find that somebody else was occupying the stage, and they could never get a real chance to say how terrible their pains were. I think that only a group expert could stand it, and if he could, then I think something would emerge from that pattern that couldn't emerge if the expert

saw those thirty people individually. I think that you can look at a group like a real cartographic map. The group theorist can learn to "read" the group.

Banet: In your book you use the analogy of a clock. It is possible to understand the individual parts of a clock, but you would not necessarily know that their function was to tell time until they all came together.

Bion: It's true. It's like the process of a group. It's more than likely that the group process will tell you all about something that your innards could tell you – such as hunger – something you don't know cognitively. I think that the person who takes a group, the group specialist as it were, should be able to detect a pattern that may not be obvious to the rest of the group.

Banet: I associate that expression – "taking the group" – with you. Other people speak of "doing" groups or "leading" groups, and it is very clear in your writing that you "take" a group. You are observing something that you didn't create.

Bion: One should always remember that, in fact, every member of a group "takes" a group if one could only see it in that way. The fellow who sits there and doesn't say a word from start to finish "takes" the group and exerts an influence on it. Sooner or later, somebody will notice: "You haven't said anything." Then he might ask, "If you come here week after week and don't say a word, what are we supposed to do?" But it is obvious that this person is in his own way taking a group – and yet he can say, "I've done nothing."

Banet: I have worked with groups in many different ways. When I am more personal and inviting, I'm pretty calm inside. But whenever I consult with a group in the Tavistock manner, I am frightened, especially at the beginning. It seems ominous – that perhaps something terrible will happen. It seems that in such a group there's always potential for terrible things happening.

Bion: In psychoanalysis, when approaching the unconscious – that is, what we do not know – we, patient and analyst alike, are certain to be disturbed. In every consulting-room, there ought to be two rather frightened people: the patient and the psychoanalyst. If they are not both frightened, one wonders why they are bothering to find out what everyone knows.

I sometimes think that an analyst's feelings while taking a group – feelings while absorbing the basic assumptions of the group – are one of the few bits of what scientists might call evidence, because he can know what he is feeling. I attach great importance to feelings for that reason. You as an analyst can see for yourself what a shocking, poverty-stricken vocabulary it is for you – I'm frightened, I feel sexual, I feel hostile – and that's about it. But that's not what it's like in real life. In real life you have an orchestra: continuous movement and the constant slither of one feeling into another. You have to have a method to capture all that richness. In a group, you are in the unfortunate position of having very little evidence. The physician, the physical person, can get physical evidence, or so he thinks, anyway. When dealing with physical things, you can touch, you can feel, and you can smell, but we who use our minds are really up against it, because we don't know what the mind really is capable of perceiving. Even senses that were available to us at some stage in life we have lost.

Some sea creatures retain incredible sense perception. Take the mackerel. Its sense of smell is long range, so it can collect food because it can smell decaying matter, whatever it is, wherever it is, and can close in on it. Our own sense of smell seems to have deteriorated very considerably, and in fact, in order to get any kind of acute smell, you have to live in a watery element.

When human beings are born, they change from a watery fluid to a gaseous fluid – the air. The person takes some kind of fluid with him in the form of mucus; the nose can still operate but on a greatly diminished level. Of course, if there is too much of it, then we have what we call a catarrh and the watery element drowns our sense of smell.

Banet: So the person who takes a group is sniffing out or relying on some special sense.

Bion: Well, I think it would be very wise to suppose so, and it might be possible to get more and more conscious of what this special sense is. Suppose you were observing a group of – say – Russians. You might say, "These Russians – they never smile, they never laugh." Well, if you're used to using these small muscles here around your mouth then you certainly notice it when another person doesn't use them. It may take you some time until you realize that they don't use their small muscles for smiling but they use something else – their

feet or something (they may be dancers) – and express a smile in that way.

Banet: A fantasy I had travelling here to meet you was that you would look like Basil Rathbone dressed as Sherlock Holmes – a detective, constantly alert to every minor cue. It sounds like the group consultant is a detective, skilled at being attentive to nuances.

Bion: Well, I think it is important to be able to develop that skill – to be able to sort out the information. Take a room like this. You can be aware of it, and if you're very observant you can have a pretty good memory of the things that are in the room. When you have masses of data, you can even say, "I went to their room, and I don't think that they are particularly aesthetic people." Well, that's an interpretation of these material objects. You've got to be a gatherer of your sense impressions, but it is fatal if you allow yourself to be drowned in impressions – so much mucus, so to speak, that you can't even smell – so that instead of your perception being an advantage, it becomes a liability. I think that this is the complaint that so many Frenchmen feel about Victor Hugo. When André Gide was asked who was his country's greatest poet, he said, "Victor Hugo, alas." Well, it's incredible – Hugo's observations; they're really extraordinary. The visual images he's able to carry off are impressive, but you don't get the impression of Hugo as a great thinker, because he doesn't seem to synthesize it. It leaves the reader to synthesize his observations.

Banet: That would be one function of theory – to provide that synthesis of impressions. I would like to hear you talk about large groups – institutions and organizations.

Bion: Institutions and organizations are all the same – they're dead. Let me put it this way. An institution behaves in accordance with certain laws and bylaws – it has to make them – and all organizational laws become as rigid and definitive as the laws of physics. An organization becomes hard and inanimate like this table.

I don't know of anyone who can say at what point animate changes into inanimate. Take, for example, a dung heap. It seems inanimate, and then maggots appear, and it becomes animate. The trouble about all institutions – the Tavistock Institute and every one that we have – is that they are dead, but the people inside them aren't, and the people grow, and something's going to happen. What usually

happens is that the institutions (societies, nations, states and so forth) make laws. The original laws constitute a shell, and then new laws expand that shell. If it were a material prison, you could hope that the prison walls would be elastic in some sort of way. If organizations don't do that, they develop a hard shell, and then expansion can't occur because the organization has locked itself in.

Banet: Currently, there's a lot of interest in trying to get organizations to be more responsive to human needs. Does that have some chance for success?

Bion: If the organization does not respond to human needs, either it or the individual will be destroyed. It's like an animal that protects itself by growing a hard shell. What's going to happen when the animal grows? What's going to happen to either the shell or the animal? The ordinary bird has sense enough to crack the shell and walk out.

The curious thing is that the mind itself seems to be able to produce a shell of its own. People say things like "I don't want to hear any more of these new ideas. I've been very happy. I don't want to have my ideas upset. If you start making me think of this and that, well then, I might have to bother about the troubles of Los Angeles. Why can't I live here in peace and quiet?" I think there is always a resistance to development and change and a tendency to think what a horrible thing this maggot is that tries to animate the dung heap.

Banet: Institutions that have been around for some time, like the United States or the Catholic Church, profess an interest in renewal and changing, but then it seems like perverse things happen. Either the leaders are removed or people become very pessimistic about the possibility of change.

Bion: I've often thought that the United States has an intellectual belief in itself as the "top" nation. There is a feeling, therefore, that the institutions that are all very well for an unimportant or beginning nation are no good at all to one on the top. I think that there will be a tendency to rebel against this restraining force, this invisible shell, which is so difficult to imagine – even to conceive of at all.

One just does not know what the restraints on a nation are. In the early stages, they were fairly clear. It was quite easy for Americans to see the British as the restraining force and to rebel against that. But then, this newly formed institution started growing a shell again. Its

new laws and Constitution were enshrined. Now a feeling has developed that the Constitution – which is the mental shell of the United States – isn't really adequate for the world as it is, because the nation is growing and is aware, therefore, of the pressure and the hostility that come from outside. The people of the United States may want to live in peace; they may not want to attack anybody; but then they find that they have to have a navy; they have to have an air force; they have to have an army – all of which they may hate having. Once again, a shell within a shell starts growing. They have to have a secret service. Then suppose they feel that the secret service and the police want to know what they're up to, but they don't see that it is anyone else's business. So they can be aware of the very shell that they're growing while it is growing. That is obviously a most uncomfortable proceeding, because you can hate the shell and yet believe that it is necessary. For example, I don't want to be invaded by some foreign country. All right, then I'll put up with the army, navy and air force, but then the army, navy and air force say they want me as a recruit and I must learn how to bear arms. I hate the shell but come to see it as necessary.

Banet: At the time of the political assassinations there was a lot of editorial comment to the effect that "we are all guilty", that an assassin has some valence with the rest of society – he acts for all of us.

Bion: I think that one needs to beware because that judgement can be made too prematurely and precociously. If one judges prematurely, then he clamps down on it – adds another shell. I can see this with myself. The more tired I am, the more quickly I give interpretations. It's such a frightful business to retain your freshness of mind; the mind goes on working even though you don't have the foggiest idea what's going on.

That's why one tries to learn and take some sort of scientific, religious or artistic approach to the problem of history – it's simply difficult to visualize what on earth the problem is in this country. One can only get these somewhat trivial models that one picks up from the past.

Banet: I know that you are concentrating on individual psychoanalysis, rather than on groups, and that you have written recently on the problem of knowledge and perception. What is exciting for you these days?

Bion: I'm working mostly with individuals now. The investigation of the individual still has a lot to yield. The advantage of the group is that you can see certain elements much more easily. With the individual, you may find it very difficult to see disturbance; the patient is so rational, so calm, so all right, that you are misled by this surface appearance. As Virgil described it in the *Aeneid,* Palinurus, although tempted by the God of Sleep, is not taken in by the deceptively calm and beautiful exterior. When the analyst allows himself to be deceived, he will say, "Well, this patient has never had any troubles, has never been any trouble, always got on well, is loved and liked by all of us, and is a very affectionate and charming person. I can't understand how or why he should commit suicide." That, of course, is a very dramatic thing – when a person brings his life to an end without anybody having observed what was going on. To see what's inside – that's the difficulty.

I am interested in the individual – in his struggle against the pressure from the shells built around him. We talked about the shells of organizations earlier. Well, individuals have shells too. When you are dealing with a mind, or a personality, then you get these same shell-building processes, but they're much more difficult to deal with because you can't fall back on physical observation. Perhaps if you were more sensitive, or you employed more sensitive instruments, you could do it, but not as things are at present.

If you have an active mind, it is pressing against the obstacles and restraints to its operation, and every activity, or your own personal fatigue, puts a restraint on you, so you can't even locate the shell. The inhibition of one's self produces difficulties. It would be so simple if one could say, "Oh well, you're suffering from these inhibitions, and we all know what Freud said about inhibitions." But that isn't all there is to say about inhibitions. We have this vast universe and we have various objects scattered about, but the outside world is out of our control. It is simply out there. However, we have some choice about what to pay attention to. This means that I have to split things up – table, lamp, and so on. If you think of it in slow motion, you have to choose the order of precedence. So when you choose to try to get out of your inhibitions and restraints you are up against a problem of splitting things up – calling this object a book and saying this is a table. I don't know that that would be agreed to by the person who has concentrated on the atomic constitution of the thing, because

where should the table end? Where can you say on the one side is a table and on the other side is air?

Banet: Well, it seems that I might come up with a practical solution. I might believe that the table is really a collection of molecules, but I expect something to rest on it if I put it there.

Bion: That's the point. One has to come to a practical decision; at some point we have to translate our thoughts and ideas into action, and, so far, we've been able to do that.

Banet: I'm interested in your thinking about the growing interest in Eastern philosophies in this country, It seems that we're departing from Western European traditions and adopting Eastern perspectives.

Bion: I don't think that we can depart from the Western European tradition, but what is so striking is that we've become aware that there *are* different methods of thinking. I don't know Sanskrit (I'm no good at languages at all), but as far as I can tell by translations, there is a most striking resemblance, say, between the *Bhagavad Gita* and Meister Eckhart – a resemblance between entirely different religions. Both of them are surrounded by this type of thinking – breaking out of one's shell – and it upsets a great many people. The *Bhagavad Gita* is still read after hundreds of years.

Banet: Eastern and Western mystical thought both suggest a reduction or destruction of the ego – that you can, in some way, break out of the shell of self.

Bion: Freud made a very illuminating observation about the ego, the id and the superego. It's only when one tries to contemplate it, tries to look at the human being, that he begins to see that these psychodynamic formulations, which are very fruitful, are really not quite good enough. But it's difficult, because one doesn't really know whether one's misrepresenting Freud or whether one's got onto the right track.

It seems to me that one could say that the mind has a kind of skin that is in contact with somebody else. For example, we are talking together. Why? How? I may quite mistakenly think I know what you're asking me and what you're telling me, but why? What are these senses? If it is a question of my sense of touch, I can say that it's the skin. But what is this mental skin that enables two people to

be (although it is a metaphorical use of the term) in "contact"? We borrow the term from the physical world, but it isn't touching. One can feel it; he can bring his mind (as Dr Johnson says) up against the other person, and he can be aware of a contact – something that he just has – with another. You have to use some words if you want to talk about it at all. This contact requires labelling.

Banet: I'm certainly aware when I'm not in contact with someone.

Bion: But it is very difficult to know why we know that.

Banet: The philosophical aspects of your work are really where a lot of your attention is. I can see you playing with concepts – putting things together. I'm interested in hearing more about that.

Bion: I'm not sure that I can find the passage. In the *Phaedrus*, Socrates points out that language is extremely ambiguous, and therefore difficulties are produced when you have to turn your thoughts into action, which is unambiguous. The two of us (two entities, characters or personalities) meet – what are we to do? Usually it isn't an acute enough problem to be noticeable, because an attempt can be made to talk the same language. But supposing one found himself on a desert island with someone he'd never met and whose language he didn't know – what way would he bridge the gap? Sign languages are commonplace, but nobody has really studied how, in fact, contact is made.

Banet: I would put my money on some kind of collaborative action or work.

Bion: That's the important thing about the group approaches – it may be possible to detect what this work of making contact is. The group has to find some way in which it can meet again – some method of communication between the various members who are physically discrete, different people. It seems that you end where your body ends, but it's a very puzzling situation. People can meet and talk and extend themselves into one another. There even seems to be a kind of communicating that extends over the centuries between Plato and the *Gita* and Meister Eckhart and us.

Banet: Religion has some explanation for that – the spirit.

Bion: Because religious people have been at it a long time, they have a considerable vocabulary, although we could say that it isn't

adequate. You'd have to invent some sort of extension; you'd have to burst out somewhere. To me it appears that you would have to have this little pimple that you call psychoanalysis appearing at the surface. The trouble is that we are so limited – we analysts think that if we are a part of the pimple the rest of the body doesn't exist – that the religious world (whatever it is) has ceased to exist. Psychoanalysts have been particularly blind to the topic of religion. If we try to extend – if we happen to be at the edge of the growing point – it's absurd to imagine that there isn't anything behind that or that there isn't anything that we're pushing against.

This brings us to another point. If psychoanalysis is a kind of extension of the religious world, then the religious world would object to that extension. The Jew might wonder about this distortion of the Hebrew tradition called Christianity. You get the same thing over and over again. What are these newfangled ideas – psychoanalysis, psychology, groups, therapy? They're all fallacious. "All this has been known by the church for hundreds of years" would be a common reply. Alternatively, "This is dangerous and heretical. You'll destroy religion if you start introducing sex into things."

Banet: It seems that at a later stage the church somewhat embraces psychoanalysis and incorporates it into its training.

Bion: Yes, but it does seem to be the same process of getting a sufficient shell to be protected and then having to rebel against a shell because it not only protects you, but also can shut you up. The shell that protects also kills. Let me put it this way: individuals can be so rigid that they don't seem to have any ideas or they can be so free and so profuse in their outpourings of ideas that it really amounts to a pathological condition. But the same things seem to me to apply to the state or to any organization. People can't just easily escape and take up a new mission and still maintain that they're members of your organization. On the other hand, people outside shouldn't be allowed to say they are members of your organization and use you in order to gain a sort of cloak of respectability for their ideas. So there's the problem. How permeable are you to make this envelope of self, this shell? Or to get back to the Freudian phrase, how permeable is the ego to be? There are pressures from inside and, on the other hand, pressures from without. To what extent is one to allow any idea to come in? One feels that there's a need for a sort of discriminating screen.

If it were physical, one could try to invent some sort of sieve that sieves off what one doesn't want and allows in what one does want in. When it's the mind, I don't know how it could be done.

Banet: It sounds like you're regarding your work, especially your book *Experiences in Groups*, as just a beginning. Many other people regard it as a definitive piece of work.

Bion: That would be a great pity. The book is not the final view, and I urge people working with groups to make it out of date as soon as possible.

Banet: I have a feeling it's going to be a while before it's out of date.

Bion: I am sure certain basic things in *Experiences in Groups* are worth retaining. I hope that is true; otherwise, we could be leading people up the garden path. I hope that there are certain things that are still operative, but to allow "Bion's theory" to operate in a rigid way such as print would be ridiculous, because that puts a restraint on the growth of the individual and the individuals who make a group.

Banet: In the past few years, the A. K. Rice Institute and its centres have become more popular; there are more people going to group relations conferences and learning about groups and your theory. Is that gratifying to you?

Bion: It doesn't make much difference for me, in one sense, because I'm out of group work and I'm still working on individuals very much; but I certainly think the work of the Institute is very important. But, again, the Rice Institute must realize that it is not going to be exempted from the problems that confront the great organizations like the United States or the individual states.

Banet: It's subject to the same problems.

Bion: The same problems . . . You've got to have these rules – these bylaws. Of course, one can make new laws so there's got to be a certain flexibility, but, unfortunately for organizations and institutes, it's difficult to be flexible.

Banet: Are you going to write some more about groups?

Bion: I hope so, but, you know, one of the difficulties today is finding the time. At present, I am heavily committed to my work with individuals.

TAMING WILD THOUGHTS [II]:
UNTITLED
1977

The two untitled transcripts in ‘Untitled’ were first published in 1997 in *Taming Wild Thoughts*, edited by Francesca Bion (Karnac Books, London).

EDITOR'S INTRODUCTION

Taming Wild Thoughts is a short book of just 56 pages, consisting of Bion's 1963 paper 'The Grid' and two untitled papers. The two transcriptions from May 1977 have been extracted from the original 1997 booklet and are published here to be together with the papers from the 1970s. Accordingly the parts of the original Foreword by Parthenope Bion Talamo have been divided between this volume and Volume V, in which the 1963 paper 'The Grid' now appears.

Taming Wild Thoughts [II]

Untitled

FOREWORD

Parthenope Bion Talamo

The two transcripts seem to have been intended as the first chapters of a book of which no more is known; the recordings were made on two consecutive days in late May 1977, when *A Memoir of the Future* (1991) was already finished and Bion was working on his autobiography, but they are different in kind from both of these. In the first 'chapter', he takes up the idea of stray and wild thoughts and how to capture them and introduces the concept of beta-element, in an almost whimsical fashion, as a 'box' into which to put one sort of captured stray. The discussion that develops links up with the Grid, as it deepens and develops the notions of alpha- and beta-elements, dream thought, and rhythmic, non-verbal communication. Bion goes on to show something of what he had in mind when he talks of language achievement, as a sort of high-point of sophisticated and efficacious communication, and then returns to the physical level, beta-elements, ending with a discussion of archaic vestigial aspects of the mind. The style is very discursive – conversational, almost – and might be thought of as rambling, but it is in itself a good example of the validity of the 'large circumference' of a circular argument, since the return to the theme of beta-elements towards the end of the chapter is notably enriched by all that has occurred 'on the way'. (I have often thought that Bion's concept of a circular argument was well illustrated by the circular form of Joyce's *Finnegan's Wake*.)

The second 'chapter' takes up the problem of evaluation; starting again from sensorial data, beta-elements, which Bion seems to assume in a relaxed sort of way as a non-questionable 'given' on which to build his architectonics of thought, he moves on to the question of psychoanalytic supervision. Several points come up for discussion on the first section, which might be headed 'speculative

imagination' – another term for wild thoughts: the relevance of the past only inasmuch as it obtrudes on the present; the deep and profound respect for the patient's present, for his presence in the room, and for the experience of this, which the analyst can have if he allows himself to do so; the noxiousness of hopes and fears, tying up with memory and desire but from a slightly different angle; the minimum conditions necessary for analytic work to be done.

The second section takes up the theme of speculative reason – that is, the discipline that has to be applied to the speculative imagination – and is followed by a brief sortie into what Bion calls reconstruction, but which turns rather rapidly into a short essay on theory leading on to a discussion of unconscious thought that has never been conscious, dubbed the 'inaccessible state of mind'.

Turin
7 April 1997

INTRODUCTION

The following pages are transcripts from two tapes recorded by Bion sitting alone in his study, thinking of his forthcoming visit to Rome in July 1977, to give talks and hold seminars. (Those seminars were published in 1983 in Italian by Borla under the title, *Seminari Italiani*, and in 1977 by Karnac Books in London.)

He speaks in a relaxed, reflective, meditative way, though it is clear that he is not talking to himself but to an imaginary, attentive audience. He sees himself 'idling away my time', thinking in an 'almost thoughtless' way, and then looking to see what he has caught in 'the net of my idleness'. But these verbal cogitations are far from the lazy meanderings of a day-dreamer; they are clear, sharp, and disciplined and tinged with his individual quirky sense of humour. Wild thoughts are domesticated, and stray thoughts are found a home.

The themes are all familiar ones to be found elsewhere in his writings, but he seldom repeated himself word for word; there are variations, expansions, additions, and some vivid metaphorical passages.

Only minor editorial changes and corrections have been made, mostly with ease of reading in mind. Both days' recordings ended in mid-sentence; the tape ran out, not the speaker.

Francesca Bion

28 May 1977

If a thought without a thinker comes along, it may be what is a 'stray thought', or it could be a thought with the owner's name and address upon it, or it could be a 'wild thought'. The problem, should such a thought come along, is what to do with it. Of course, if it is wild, you might try to domesticate it. I shall consider later how you might try to do that. If its owner's name and address is attached, it could be restored to its owner, or the owner could be told that you had it and he could collect it any time he felt inclined. Or, of course, you could purloin it and hope either that the owner would forget it, or that he would not notice the theft and you could keep the idea all to yourself. If the owner is prepared to allow you to have it, or if it was understood that you were quite entitled to keep it, then you might try to train it in the way it should go and in a manner that would make it more amenable to the habits of your own resident thoughts and to the thoughts of the community of which you were a member, in such a way that it would gradually become assimilated and part and parcel of the totality of the group or person in whom the thought is to continue its existence.

What I am concerned with at the moment is the wild thoughts that turn up and for which there is no possibility of being able to trace immediately any kind of ownership, or even any sort of way of being aware of the genealogy of that particular thought.

First of all, it seems to me to be simplest to try to tackle the problem by considering what this strange thought is. We might get a clue to it by wondering in what frame of mind or in what conditions this wild thought turned up and became enmeshed in our method of thinking. It could be that it seemed to occur to us when we were asleep. I am using this expression, 'when we were asleep', because it

is a state of mind with which most people think they are familiar, so we can start with this somewhat familiar idea.

I want to consider the peculiar state of mind in which we are when we are asleep or, as is also frequently said and which has even become commonplace of psychoanalytic thinking, when we are unconscious, meaning by that when we are in a state in which we are not aware of our thoughts and feelings – or not quite. There are also some peculiar events that take place when we are asleep which are notorious and which are historically known to us, both in our private histories and in the history of the race. They are often said to be dreams. But I think it is as well to consider that it might be much more compatible with the events that take place if we could say to a person who reports that he has not been anywhere but has been in bed and has slept well and so on, that what we would really like to know is where he went and what he saw during those hours when, according to him now, he was asleep. It is more than likely that he would reiterate that he went nowhere – he simply went to bed. But it is possible that he might also say, "Well, of course, I had a dream – but then, it was only a dream".

Freud was one of these peculiar people who seemed to think that dreams are worthy of further consideration. This has often happened. In the Book of Genesis dreams have been reported, including what are supposed to be interpretations of those dreams. There are other similarly well-known reported events, for example in the Book of Daniel, in which actual figures have been reported – mina, mina, and half minas – which seem to be straightforward enough because they are applicable to weights and measures. However, there was something about them that led the dreamer – namely the person who picked up what I call this 'stray thought' – to feel that these words had some meaning other than the obvious one. Why he should think so, I don't know, and we never shall. But he actually found somebody who appeared to fall in with his idea and who gave the words an interpretation that, so it is said, turned out to be correct.

I want to leave it aside for a moment and not consider that matter any further than just to remind you of the existence of this peculiar state of mind where we see things and go to places which, when our state of mind changes because we happen to do what we call 'wake up', we then ignore these facts, these journeys, these sights, on the grounds that they are only dreams.

In case one of these strays comes along, I think I shall try to be

prepared for its reception by arranging certain categories that might be suitable for placing the stray in a temporary – what? It is difficult to find the word for it. I do not find that the vocabulary that is available to me is suitable for the purposes for which I want it just now, so I am going to call it a 'box'. The first box I am thinking of is really not suitable for anything so ephemeral as what I usually call a thought, namely, something that is physical; I shall call it a 'beta-element'. I don't know what that means and I don't know what it is, and as it hasn't turned up I am still ignorant. But anyway, there it is, in case that strange creature should exist and should it swim into my ken.

There is something a bit more sophisticated: that is to say a similarly physical creature, but one that arouses in me primordial thoughts or feelings, something that is a sort of prototype of a mental reaction. These I shall call 'alpha-elements'. I likewise don't know much about them, but I think I have been in states of mind in which I am aware of their existence. That is to say, I have what I call a stomach ache or a headache, or I am possibly told that I have been extremely restless and have been tossing and turning around. I remember this on an occasion in which I was amused to hear that in the school sanatorium I had been in a state that was really rather impressive; I was told I had been delirious after an accident. That gained me a certain prestige amongst my fellows that I had been so seriously ill. During this stage I had actually picked up a chair and hurled it across the room – luckily not hitting anybody.

There have also been these occasions when I have again fallen into the prevalent idea of saying that I had a dream, but I can only say that I felt physical pain – my arm ached; I even had some kind of reminiscence, after waking up, that my arm was stiff. That is the kind of thing, should it turn up, that I should like to put in this category.

There is another one in which I am nearly awake and nearly asleep; there I have certain ideas that are comprehensible to me when I am fully awake and of which I can tell you exactly, in terms of verbal formulations of visual images, what I say I dreamt or saw in my sleep. By this time I think I could consider that I am in a different state of mind, namely a conscious or waking frame of mind. Again I am in difficulties because I don't in fact know what to call it, but perhaps you might be able to grasp my meaning. Perhaps it would be better at this stage if I took the precaution of going back again and resorting to numbers, calling the beta-elements 1, the alpha-elements 2; these

pictorial images and so forth I could put into the category of 3, or C. It could be A, B, C; 1, 2, 3, and then D4, E5, F, G, H. . . . Becoming wider and wider awake, I hesitate, because I would like at the same time to have these boxes available for rather different, or apparently different, creatures, so that I could consider what could be called, mathematically, the negative versions of it. They could be marked H–, G–, F–, E–, etc. down to zero (0). In that kind of way one has room for quite a zoo, quite a number of strays and thoughts without owners or with owners . . . [*a temporary break in recording*]

The advantage of what I have said so far is that I think I can put this down, record it on a piece of paper on which I could make the appropriate marks. I can try to communicate it to you.

Thinking it over, I find I am somewhat dissatisfied, and although I also feel it is very unlikely that I shall ever be satisfied, I will attempt to put my dissatisfaction to some good purpose by considering one or two other possible methods of making provision for these strays.

It occurs to me that, in case they become visible to me, I might be able to put them into the appropriate colour; for example, taking the cue from dreams that I have had, colours like the blue of the sky, the red of blood, and the yellow of ochre, the colour that is made out of earth. They are primitive colours, these primary colours, and they might be very useful. When it comes to this sort of thing which I have called a beta-element, it gets more difficult; I don't know what to call that. Perhaps, provisionally it would do to say, 'gross darkness', which is different from darkness which has a certain amount of light in it; this would be with absolutely no light whatsoever, the sort of light verbalized by Victor Hugo as *"le néant"*, or by Shakespeare [*Macbeth*, V. iii] when he talks about "a tale told by an idiot, full of sound and fury, signifying nothing" – zero, 0. I am not very happy about it because, thinking of it in a somewhat linear manner, I would like to start with these positive numbers and letters down to minus 1, 2, 3, 4, indefinitely. I think it would lead to infra-red and ultra-violet. If it were the numerological categorization, there I would have to use some term like 'infinity'. The worst of not being a mathematician or an artist is that I am very much in the position of the infant or foetus, which, I imagine, hasn't adequate modes of expression or communication, and in many ways hasn't a great deal to communicate. I suppose the infant might want to communicate that it was either lonely or hungry. And I, in this peculiar world in which I now find myself,

am both in need of nourishment and of somebody with whom to communicate, not because I have an awful lot to say, but because I find myself in the state of mind with which I am distressingly familiar – the state of mind in which I can only say I am abysmally, literally and metaphorically, ignorant. That is one reason why it is a matter of some urgency to me to be able to find some sort of network in which I can catch any thoughts that are available.

I think you can see I am already finding myself in difficulties, so I would like again to pick up some further tentative categorization that would be suitable for any thoughts. The nearest I can get to it is probably the sort of thing musicians know about and have developed very successfully. I remember seeing some kind of animal in a zoo when I was very small: it was rattling its horns on the bars of the enclosure. The peculiar thing about this creature was that it kept on entirely rhythmically. It was most extraordinary, so much so that I was able to draw the attention of a grown-up who was with me, who was himself a very perceptive man, and he agreed that this was remarkably and clearly an established rhythm that could be written down.

I am still stirred by these rhythmical communications. It is fascinating to hear a group of drummers performing; it has the same sort of effect upon me as is described by a poet when he talks about "the brave music of a distant drum" (*The Rubáiyát of Omar Khayyám*, Fitzgerald, 1859, p. xii). I remember in war being incredibly moved when I heard the distant music of the bagpipes of a Highland division that was to accompany us in battle. I have heard many different kinds of music since then, including that described by Osbert Lancaster as betraying the presence of the English army, namely, "snatches of tuneless song". When I first heard Stravinsky's music to *Petrouchka*, I thought it was somewhat incomprehensible and not very pleasing, but very sophisticated. I shall have occasion to refer to this again later on.

I have been idling away my time, thinking in this way – a way I could describe as being almost thoughtless. If, as a child, I had been caught at it, somebody would have said, "Why on earth don't you find something to do?" I would now like to have a look in case I have caught anything in the net of my idleness.

What is this first specimen? "Golden boys and girls all must, like chimney-sweepers, come to dust." This stray has a name and address attached to it – Shakespeare. ("Golden lads and girls all must, / As

chimney-sweepers, come to dust": *Cymbeline,* IV. ii.) The only address I know is Stratford-upon-Avon, but I gather he is dead anyway, so I'll adopt this piece of property that is in fact his.

I am afraid it seems terribly hackneyed to me. It is one of these things about which I could say, "Yes I know . . . yes I know", words I have learnt to regard with great suspicion and sadness. Whenever I hear the expression, "Yes I know" or "You know", repeated again and again, I find myself feeling sad, because I feel that it is going to be very difficult to get to, or to communicate, what I want to know or communicate – there's hardly room for it because everybody knows, including myself. It is almost an archaeological operation to excavate this knowledge in the hopes of finding a thought buried somewhere inside it, possibly even some wisdom.

In a way this is rather like experiences I have in psychoanalytic sessions. Patients who come to me have nearly all heard everything I have to say; they have read it in books, they have heard about psychoanalysts and psychiatrists and even cures. What they have to say to me is also deeply buried because they have become so used to saying it and knowing that it is a complete waste of time trying to find anybody who will listen to what they are saying.

The sort of excavation that would seem to be required to get through to a little bit of wisdom is so intimidating that one feels nothing short of a spade or a shovel, or nowadays even an atomic bomb, would ever get through to it. However, although I am sure that these forcible means of communication might sometimes expose something valuable, I don't think that I would advocate atomic explosion as a mode of archaeological exploration of the Ziggurat. As a matter of fact even extremely knowledgeable, wise people like Sir Arthur Evans [have been accused of being destructive] on the grounds that they have destroyed more than they have illuminated by their excavations and re-constructions. Just as the archaeologist has to be very careful when he thinks he has reached some potentially revealing object and has to resort not to a spade or a shovel but a camel-hair brush, so the analyst has to know when to discard these crude and violent methods and when to pick up something far gentler, far more revealing and less destructive than a shovel. It is difficult to know – and this is one, and only one, reason – why psychoanalysis needs to be carefully done, because the situation is so precarious and because it is so difficult to find the

minimum conditions for achieving wisdom either in oneself or in one's collaborator – namely the patient.

Let's go back to the find – "Golden boys and girls all must like chimney-sweepers come to dust", together with, "Yes I know, we all know that, and probably we are as sick to death of it as we are of other chunks of Shakespeare we have picked up in our time, or been forced to learn at school".

Hugh Kenner, by accident overhearing a Warwickshire yokel talking, discovered the further meaning, probably current in Shakespeare's time: 'golden boys and girls' could refer to the dandelion, which, when the petals have dropped, looks like a chimney-sweep's broom and is then known as a 'chimney-sweeper'. So from that point of view Shakespeare is able to use a simple phrase and simple language, which then communicates an idea hundreds of years later to people who have probably forgotten entirely the commonplace meaning of the words he used originally and which were commonplace when he used them, and transformed them into immortal phrases that last for hundreds of years and take their meaning with them. A similar state of affairs is produced by him over and over again, as we all know. "The raven himself is hoarse that croakes the fatal entrance of Duncan under my battlements" [*Macbeth*, I. v]. The most difficult and longest word in that sentence is 'battlements', and yet the total sentence conveys a meaning which is extremely depth-stirring and provokes profound feelings. What, then, is the language, the method of communication, that we are to employ when we want to describe, or when we want to formulate or capture, as it were, an idea that comes to us, maybe that is communicated by somebody else, but maybe comes to us in our dreams or in frames of mind with which we are not familiar whether we are awake or asleep?

What I want to express is some kind of experience that we are able to have if we are psychoanalysts and concerned with that area of thought. You might ask, what area of thought? We have to use words like 'psychoanalysis' – they are long words, ugly words, impressive words, and words that are devoid of meaning. I can only say, "You have to have an analysis to know what I am talking about, or you have to be an analyst", which is very unsatisfactory if I wish to communicate it or pass it on. We think that the analytic experience, the real thing, the basic thing, the fundamental thing, is worth preserving and therefore worth communicating to people next week, next year,

next century, and perhaps three or four hundred years later – not in order to inform them, but in order to let them see the sort of path of thought or being that stretched out in front of us, and will stretch out in front of us probably for a long time if there are any of us to see it. "They closed the road through the woods many years ago" – the ending of the poem where Kipling describes the sound of the horses galloping through the woods. ["They shut the road through the woods / Seventy years ago." – "The Way through the Woods".] We can talk about the woods that still exist, using the term metaphorically, meaning it as a method of talking about what we are concerned with now, tomorrow, and all the tomorrows, because the road through the woods is obscured by the trees and can even be obscured by the woods that spring up, so we are concerned with a very peculiar form of excavation. We occasionally come across a child who cannot learn the alphabet. Usually antagonism is aroused in the teacher because the child is so stupid, but it is forgotten that for many reasons the child may not see or understand why it should learn the alphabet. After all, I am familiar with the situation in which we have patients who cannot see the words for the alphabet, who cannot see the sentences for the words, and who certainly cannot see the spirit of man lurking somewhere behind this plentiful crop of jargon or verbal weeds that proliferate at an extraordinary pace, and in some climates flourish in such a way that it is difficult to believe there is any meaning in psychoanalysis whatsoever.

Freud was extremely impressed with Charcot's statement that when you do not understand a situation, when you cannot perceive what the diagnosis is, you should go on until the obscurity begins to be penetrated by a pattern, and then you can formulate what the pattern is that you see. With regard to ourselves, we are confronted with what seems to be a single individual. Our attention is usually focused on a recently developed capacity of the human being, namely his capacity to elaborate and use articulate speech. It is obviously a very powerful and useful achievement. But while we are in the frame of mind in which it is possible to command the use of relatively recently developed techniques like articulate speech, we also have to contend with the many obscuring words, thoughts, sounds, physical feelings, physical symptoms, in order to excavate the underlying, basic, and fundamental feature. Not so long ago doctors were very satisfied to detect the fact that a patient was suffering from a disease known as

dropsy. Having detected the disease known as dropsy, they find there isn't one: there are all sorts of diseases – heart failure and so forth. It is very discouraging in spite of the gratification that can be obtained by apparently getting that much nearer to the origin. What about the man or woman who presents himself in your office? This person is the most powerful, knowledgeable collaborator you are ever likely to find. In this lonely job one has to do all by oneself, alone, although at the same time in the room with somebody else, that 'somebody' is both the person who presents himself for assistance and the person to whom we look for the most powerful assistance we are ever likely to find.

If we are concerned with physical disease, we have to learn the language the body talks; we can look at the expression, the ruddy blush of health, 'rude' health, and distinguish that from an obscure blood disease, and so on. The human animal, unlike other species, can lie and has probably had a good deal of practice at lying and misinforming from a very early stage, because feelings of guilt precipitate a proliferation of a capacity to lie and deceive – both the person himself and whoever else might be able to detect the supposed crime that the infant does not know about, although the infant can show any amount of guilt. The question is, then, what is the mental counterpart of these lies, these statements, this deceiving blush of rude health, this appearance of athletic somatic health and capacity, the apparent facility with which a male body can display erectile tissue? Many people have been taken in by supposing that the boy or man is both potent because he has a penis and because it can become visibly erect. This is much more hidden with the woman in whom it may be more difficult to detect any signs of erection, but psychologically she may be very potent, much more potent than the boy or man to whom she looks, and from whom she expects sexual potency. We all know situations in which mothers have been shocked and frightened at discovering that their babies can cause their nipples to become erect and so find it difficult to feed the baby; the infant finds it difficult also to participate in the feeding because of the mother's dread of these peculiar sensations, which can also be aroused by supposing that the feeding baby itself shows signs of erection. Those are all physical – what the psychological or mental counterpart of it is I don't know. That is one reason why I think it is useful to consider keeping this box into which I propose to put my various beta-elements, situations that are not really thoughts and about which it is easier for me to say, "I think

I know what this patient is thinking, but I am jolly sure they would say they weren't – if they were thinking at all."

To return to a point I have already mentioned – I could say to a patient, "where were you last night and what did you see?" and they say they went nowhere and saw nothing – they were asleep, asleep in bed, and can hotly deny that they went anywhere or saw anything. I can see that if you restrict your vision or your topic of conversation or discussion to geographical movement, then it would be perfectly true that there are many places that could be said not to have been visited. What does Mandalay look like? Or Pondicherri? Or Samarkand? Or Jerusalem? Some people might give a description of it – they know what it looks like; they have travelled so much and know so much about these places and others like them that they cannot really answer my question.

What does 'sex' mean? What does 'Oedipus situation' mean? Look it up, if possible, in the position in which there are only two people, namely the analyst and the analysand. Where would you locate this story? And anyhow, what is the story? You can look it up in the dictionary of mythology if you like. I don't know why the Sphinx is so often not mentioned. Perhaps it is because the Sphinx committed suicide and we don't know whether to exercise our curiosity or whether to kill it off. We are so familiar with psychoanalytic theories that we tend to forget the basic points; so much so, that it is difficult to say what the fundamental points are. Free associations – sometimes we hear of analysis in such a way that we think what a wonderful time we are all having, wandering about amongst the weeds, plucking the wild and beautiful flowers, admiring the brambles, the bushes, and not getting anywhere near to disturbing the sleep of the sleeping beauty – the wisdom that lies fast asleep somewhere in the thickets; somewhere buried, not only literally under the mounds of the Ziggurat or the site of Ur of the Chaldees or Knossos, but what about the Oracle at Delphi? Is that voice in any way audible? Does this sound very romanticized when it comes to a question of Doctor X and this tiresome woman, or perverse man, to suppose that somewhere buried beneath these accumulations of knowledge there is some spark of wisdom that could still be blown into a flame? There are always people who say, "Yes it can. Don't do it. If you blow the sparks into a flame, you will start a conflagration, and goodness knows where that will end – don't do it." There are plenty of people who still will

say, "The world was all right till these awful Freudians and Kleinians came to it. They are the people who are responsible for all this sexual promiscuity and general disorder." As Freud himself pointed out, there is nothing new about the situation where people complain about doctors as always discovering and inventing new diseases and illnesses – they have a vested interest in doing so because, after all, they can get paid for curing them. There is a certain plausibility in it; there is plenty of room for corruption, dishonesty, fraud, but even so I think there is something to be said for what we call 'medical science'. These terms like 'science' are so debased; they are like coins in which the denomination is impossible to detect because it has been worn so smooth that it is no longer possible to distinguish the design that was originally marked upon it and that made it comprehensible.

What I want to do is to indicate the sort of area with which we are all concerned. Later I hope to consider how we are to turn our concern into activity that is worthwhile.

For the present we have to consider which of our capacities are of any value in this particular regard. We do not in fact know who the person is today, tomorrow, with whom we are meeting. What we already know and what the patient already knows is of no consequence or importance; the past is past, and anyhow that term is part of the convenience of articulate expression. The reason why we concern ourselves with things that are remembered, with our past history, is not because of what it was – although that might be quite important in its own right – but because of the mark it has left on you or me or us *now*. In what way are any of these things detectable? The embryologists say we can detect remains of a vestigial tail, branchial clefts, etc., seeming to suggest a fishy origin of a very primitive kind from which we have diverged. But if that is the case physically, I think it is possible that it might also be mentally; there might still be traces in the mind or character or the personality, *in the present*, of particles that have a long history, things that we would expect to be fundamental, basic, primordial.

Do any of these remnants betray themselves in what we can now observe in the human speech of the person we are talking to, as well as in ourselves who are doing the talking? That is what seems to me to be one of the fundamental discoveries of psychoanalysis: archaic states of mind, archaic thoughts and ideas, primitive patterns of behaviour are all detectable in the most civilized, cultivated people;

in more primitive people we would expect them to be less hidden. These archaic elements may turn out to be of some consequence today; suppose, for example, that the remnants of a branchial cleft could develop into a branchial cleft tumour. In this way there can be certain detectable archaic elements in our personalities or minds, which are really survivals and which are capable of proliferating in a beneficent manner, but also in a cancerous manner, a pathological manner. That is the only reason why it seems to me to be interesting to be seeing a patient today and tomorrow and in the future if he or she will submit to being observed again and also . . . [*tape ends*]

29 May 1977

Anybody reading this account so far in the first chapter can see that it is hardly what you would describe as 'scientific'; that is to say, it could be seen as something that, according to the individual who is reading it, can be assessed as imaginative, or fanciful, or imitation science. It is a matter of opinion. I mention this point because these opinions have to be entertained when one is attempting to evaluate – whatever it is: whether it is the physical appearance of a person, or whether it is his character that seems to be betrayed in what he says or writes or does. In short, we are making a kind of interpretation of what evidence is brought into us by our senses. There is still the fact that it would be helpful to know what the quality of the information is which is brought in, because we depend on evaluating that evidence. First of all we have to evaluate the value of the actual gathering mechanism. I, for example, have now a good deal of experience on which to base my opinion about how reliable I would consider my impressions to be, and how healthy I consider my ability to see, how accurately my eyes work, and so on.

Although it is possible to divide this discussion up when it is a question of talking or writing, making these verbal transformations, we cannot in fact divide up whatever it is we are in contact with and which we wish to assess and to understand; that is not divided up, not even in any way, although I suppose you could say you 'heard' it, or 'saw' it, or you heard somebody 'say' it. Those divisions are more applicable to the machinery, the personality and its equipment, which is gathering the information, than it is to the universe in which we exist. The universe does not obey the laws of articulate speech, or the laws of optics, although we consider that the laws are approximating to light itself. But it is questionable how much of the laws apply

to the actual objective phenomena and to what extent the laws only apply to, or are largely significant of, the human capacities. We shall see later that this is true of a number of different activities that we can talk about in the sense of our logical capacity as well as our capacity to feel and think and observe.

This introduction is itself a pause in which I am attempting to evaluate what I have already said in the process of continuing to talk, to think about this subject.

I am not really attempting to assess the nature of the information that is brought to me by my physical senses, what I would call the beta-elements, material that seems to be more physical than mental. I know nothing about it. I merely suppose that it exists; I merely suppose that it is on a structure of that kind that I have built up the whole system, architectonics of thought. So I shall go on from this point, which I could describe as an operation of curiosity, a fact-gathering tendency, to the nature of the facts I gather, and then to the communication of such information as I consider my activities have gleaned.

The point at which I am starting is what I could call speculative imagination and speculative reasoning. For the moment I would like to divide the two into categories that I could describe, borrowing from mathematics, as sub-sets of a main set.

First, I would consider speculative imagination. What sort of value is to be attributed to that? My own impression is that it is very important. When I have attempted to supervise people who want to come to me for analytic supervision – part of a learning activity – I suggest they should not bother very much about what I or anybody else might think about their contributions, but should proceed to say what their interpretation is of the material they have told me. I find they are invariably very suspicious and very anxious to give an interpretation that has the blessing of some psychoanalytic authority, or that they think I might approve of if I were a psychoanalytic authority of sufficient importance and consequence. I won't bother to consider the nature of that authority, because I know quite enough about myself to regard the tendency to believe that I am a psychoanalytic authority as very misleading indeed and obstructive to progress. I stress this point: "Please say what you like; please say what you think or imagine is the meaning of what you have told me." The reason why I say this is not because I am suggesting that all you have to do is to disconnect your mind from your jaw and allow your jaw and your

tongue to waggle. That is not my idea, but I think it is a preliminary; even before we are able to think very much, or have enough capacity to be able to think, we should learn to be able to let our tongue and our jaw waggle, as I put it; even if it doesn't make much sense, it may be a step on the way to articulate speech. Similarly, these speculative imaginations, however ridiculous, however neurotic, however psychotic, may nevertheless be stages on the way to what we would ultimately regard as scientific, psychoanalytic formulations. This idea may be quite erroneous, but I put it forward because you can test it for yourselves and come to your own conclusions. From my experience it seems to be very important. When you have, as honestly as you can, allowed your imagination to play on the material and allowed yourself to state it in such terms as you can, then you can assess the nature of the product. I would say, therefore, that it is a good thing to say what you think you have seen. Never mind what your state of mind is; let's forget all that, let's have respect for the information that you gather in that state of mind, no matter what it is – whether it is a state of mind that subsequently you can assess by saying you dreamt it, or you hallucinated it, or you just painted it, or you 'doodled' it onto a piece of paper when you weren't thinking about anything in particular, or that you might, if you were gifted in that way, actually compose it or play a tune or whistle or sing it. I have heard people say it is useful for a stammerer to try singing, and then he becomes able to articulate in the ordinary manner. I regard speculative imagination as worthy of concern – never mind whether you dreamt it, hallucinated it, or whether it is an object of delusion, or – I don't know what a drawing or painting is the product of. I take it that presumably the artist saw or thought he saw what he has drawn. If we consider renaissance art, for example, we can see plenty of pictures of saints, crucifixions, adorations; when did they see them? And how could they see them so clearly that they could even put a line around them and give them colour and form in such a way that I can look at one of those things now and say, "This man saw this three hundred, four hundred, four thousand years ago"? I was able to walk into the Lascaux caves and see on the walls various marks and signs of painting and drawing – somewhat distorted, it is true, because I see them with the aid of electric lighting, which reveals very clearly their shape and colour. I don't know what sort of light they were seen in when they were drawn. Similarly, I can walk into the Elephantine caves near

Bombay and once again see the carvings that were made; again, I do not know in what light or in what frame of mind. I guess that my frame of mind is rather different from the frame of mind of the artist who painted them, in much the same way as I *think* I can understand the verbal formulations of a Shakespeare play – at least I am helped to do so if I can get very capable actors who know how to translate a printed drama into the dramatic form. I say this because I think it is sometimes forgotten that nowadays we are already dependent on fine performances, even of a Shakespeare play, before we can say we really understand it. It depends very much on being able to trust the evidence of our senses, on being able to depend on the actors to make the play comprehensible. I have quoted *Cymbeline*: "Golden boys and girls all must, like chimney-sweepers, come to dust." I have to interpret that in a state of mind that is, three or four hundred years later, fully conscious, when I am wide awake; it is quite different from that state of mind of the person who wrote those lines originally. I do not know what the state of mind was; I do not know what the English was that was spoken in Warwickshire at that time. I can only marvel at the product of a state of mind like that, as I can marvel at the state of mind of a Leonardo who sees Saint Ann, the Virgin Mary, and can see them so clearly. The best I can do is to make myself available to learn whatever it is that they might have been able to communicate when they were alive and of which they have left a record that I can still see or hear for myself.

This somewhat long-winded description is to draw attention to the fact that when you see your patient tomorrow, I do not know whom you will see and nor do you. It might be anybody. I am sure we have to have respect for that mind or personality; that seems to me to be the most valuable thing about the whole of psychoanalysis – the suggestion that the human mind and its products are worthy of attention. I am not suggesting you are going to see William Shakespeare; I am not suggesting you are going to see the writer of the *Bhagavad Gita* or some famous painter or sculptor or composer, a Mozart – we don't know. But I do suggest that you will not know unless you are able to respect the actual experience made available to you when the patient goes so far as to spend time and money coming to see you. If you are not dealing with somebody who is worth all that scrutiny, all I can say is, it is possible that it may be worth while if we ourselves are sufficiently worthwhile to be capable of learning something from

the experience. So there is always a chance that the engagements you and I have made for the morrow could be turned to good account. It may turn out to be very worthwhile because the patient is a person of some importance or consequence and has gifts that have so far not been revealed or, if they have been revealed, have been dismissed on the grounds that he or she is stupid, or psychotic, or crazy. The same thing may apply, although it is now unlikely, to ourselves – unlikely because most of us have lived quite long enough for some sort of gift to have made itself manifest by this time. Let us hope that analysis has afforded us a chance, by becoming psychoanalysts, to betray such abilities as perchance we have. I am bound to say that I think it is a matter of optimism; I don't think a great deal of importance can be attached to any hope of that kind – not as far as I myself am concerned. But on the other hand I don't think that we should be obstructed either by hopes or fears. If hopes are dupes, fears may be liars;[1] so we have to have respect for ourselves and for the analysand.

The point is important because I find psychoanalysts have difficulty in realizing that there are minimum conditions necessary for the activity we call psychoanalysis. Some of those conditions lie within our own control; that is to say, we can avoid being in an unsuitable frame of mind; we can avoid being a prey to what I can most easily describe as a state of rhapsody, of being in such good humour that we allow all our emotions and wishes and desires full play. That is not much more use than it would be to arrive heavily drugged, literally with alcohol, or metaphorically with our optimism or pessimism or despair. In this respect it is therefore important to be rid of our memories and desires.

As regards supervision, it is a good thing not to look to the supervisor to give information or knowledge about psychoanalysis. In so far as it is possible to pick up an idea or two in a supervision, or even in analysis, it may be just as well to forget them when you are with the analysand because if you don't, then your mind can already be so filled with your wishes, desires, theories, expectations, that there simply isn't room for an idea; there are no interstices through which what is available to your senses can penetrate to your capacity to understand. I am not going to bother you at the moment with what this capacity to understand may be; that is another matter we have

[1]From Arthur Hugh Clough's poem, 'Say Not the Struggle Naught Availeth'.

to consider later. It is something that has been discussed and debated for many centuries, even before psychoanalysis was ever heard of.

The analyst needs to be divested or denuded of his memories and his desires so as to leave room for him to be open to the present – what I call the present. Psychoanalysis gives the impression, by which I think we are liable to be misled, that what is important is the past. The past is not important, because you can do nothing about it; the only things about which you can do anything are the remnants, the vestiges of the past, of past states of mind or archaic parts of our physical make-up – the branchial clefts, the vestigial tail, etc., our simian ancestry – but it is possible to make use of these vestiges that are discernible in the present if we allow ourselves to discern them. Even physically it may be useful to have some kind of remnant of knowledge about embryology if we are trying to assess a patient who comes complaining of some tumour of the neck or other physical symptoms that have begun to obtrude.

Our position, as I see it, is that although we tend to have shifted our observations away from the body to the sphere of the mind, the body has not ceased to exist. Because we try to make use of the facts that the patient reports by turning them into what we call 'free associations' that we can then interpret, it doesn't mean that the facts weren't facts. Patients sometimes say, "But isn't it reasonable for me to feel this when I told you what I have been seeing?" Of course I don't know whether it is reasonable or not – that is up to the patient. I am in no way doubting the accuracy, or that he is not sincere in believing that he has given me an accurate description of what he has seen, but I am disregarding those aspects of it because he knows more about it than I do. I am trying to look at something else, to hear something else, to be open to something else – vestiges, mental vestiges. I don't know where they come from; I don't know where the patient comes from. I don't mind whether he has given me his name and address and telephone number, because that is not of immediate consequence – it is important for obvious reasons, but because it is obvious it is not important – what is obvious is obvious, and there is nothing more to be said about it. The patient can have his own opinion of what he can see and know for himself; what is much more difficult for him is something he cannot see, and that is why he has come to me. Patients have difficulty in understanding that they

have *not* come to me because they know the answer, in spite of the fact that we often hear people say, "Yes I know . . . yes I know . . . yes I know", and "Well, I knew that anyway". That kind of statement is indicative, it is a sign, it is what we might call a symptom to which the analyst pays attention, not because there is any difficulty about the grammar or syntax being employed, but because it is revelatory, or could be potentially revelatory, of a state not so far discerned or of which the patient is not aware.

It is important that the embryo–analyst, the candidate, should dare to use his imagination and dare to try to articulate it in a supervision. That is one reason why I regard a supervision as being possibly valuable; if only those who come dare to say what they think and if only they will use that occasion as a way of practising trying to articulate what they think, either in verbal terminology or if they find any other, I am perfectly happy. A patient once said to me, "If you only had a piano here, I could play the thing to you; I can't talk like this to you." If I could understand music, I should be very glad for him to do so, but here again, there are these minimum conditions that are necessary for analysis. After a time I begin to know what the minimum conditions are for *me* to do analysis. The same thing has to be determined by any other analyst. It is a great mistake for an analyst to lose sight of that fact. You can make concessions if you want to; you can relax your own rules if you want to – temporarily, at any rate – but that is a matter of opinion and a matter of judgement. But generally speaking, what you have to know is what your minimum conditions are. For example, the patient may think he has the right to drag you out of your chair, or to wrestle with you, or even sometimes to use firearms against you to make what you have to say inaudible. The analyst must be clear in his mind where he draws the line, where the minimum conditions for him to analyse have ceased to exist because they have been so eroded by denial. This crops up with a child who does not know how to behave in the analyst's room, and the child's parents very often don't know how to behave with regard to the analyst who is trying to analyse their child. But the analyst has to be very clear and quite firm in stating his minimum requirements, without which it becomes impossible for him to do analysis. That is the only reason for exerting a certain discipline; not because we want to prevent anybody from doing whatever they like; we don't even

want them to come for analysis, necessarily. People are free to take up an analysis if they want to do so, but we are also obliged to say what are the conditions we have to have in order to be able to fulfil that aim.

The point we are discussing and to which this is relevant is this matter of speculative imagination. Unless the analyst allows himself the exercise of his speculative imagination he will not be able to produce the conditions in which the germ of a scientific idea can flourish. We have to bear in mind that even psychoanalysis itself is at the beginning of its career. It is only quite recently that the human race has learnt how . . . [*break in tape*]

There are many different kinds of language; some forms are hardly to be translated into articulate speech, because they are not really articulate forms of communication. Chinese, for example, has a great many hieroglyphic signs. Not only is it true of their language; I think there can be a conflict between, say, Chinese and Russians, although superficially there can be agreement, apparently, between their ideas of the way in which the human race should be governed. But the Chinese, with their hieroglyphic method of communication, also attach a lot of importance to the small muscles of the face and are prejudiced in favour of communications with people who allow themselves facial expression – muscular expression – when they talk. They don't like people whose faces are impassive. So there may be great agreement between the ideas of different races, but great differences that are not openly expressed because they are expressed in muscular ways, physical ways. In the famous guide book on Spain, Ford (1845, Vol. 1, p. 83) gives a good description of the gestures commonly employed – the gestures of the hand, etc. It is extremely informative and shows how much importance would be attached by two people, talking to each other, to what they say and how that is accompanied by movements of muscles – hands, face, etc.

The analyst has to be quite clear, or as near as he can get in the course of time, as to what are the minimum requirements on which he proposes to exist. For example, I feel that if anybody wants an analysis they will have to come to my consulting-room, because I have not the means by which I can get to theirs, or the time. It is not because that is a particularly good thing for the patient, it simply happens to be the limitation imposed on me by my own limitations. I have to say,

"I shall have to ask you, if you want to try this, to come to see me here at a particular time, for another session, or two more sessions." But of course it is nothing like as simple as that; there are so many things which are not easily formulated, and it is not until you know what the patient is capable of in the way of communication, obstruction, hostility, that you can be quite clear whether you can stand it or whether you can't. The reason for discussing the matter at all is because you need to be prepared to say to the patient, "thus far, and no further" – not because you want to stop him from doing anything he likes, but because you understand that he wants an analysis and you know whether or not you can do analysis in the conditions the patient is proposing.

On the way to being an analyst, you have to reserve the right to indulge your speculations, your speculative imagination. Perhaps you might want to sculpt, or paint, or draw, or compose music or fiction, in order to give your imagination an airing, to give it a chance to develop into something that might be scientific.

Another sub-set: speculative reason, similar to the other. Here again, you can give your reason for whatever it is. Reasons are extremely prolific, they flourish, they crop up like weeds. As I said earlier, they can be like brambles that proliferate so vigorously that they make cultivation impossible. This means that in the course of this speculative imagination, speculative reason, there is no particular reason to prevent – and I think every reason why we should not prevent – your speculation and your capacity for reason from exercising itself. But I think it should not be allowed for too long to be purely a sort of rhapsody, purely a state of affairs such as Valéry describes: it is imagined that the poet goes to sleep or indulges in a drunken orgy and wakes up to be able to write down a poem. He says that that is not the way in which poetry is written; in fact the poet has to be much nearer to being a mathematician. So while I say that it is extremely important to exercise your imagination, to let it go, to give it a chance to flourish, at the same time keep it under some sort of discipline.

At some point, while you are exercising your imagination, you are trying to imagine what sort of person this is that you are making contact with. When the person comes into your room, it may be possible to answer that question starting with the answer – the name and address and telephone number, etc., of that person. But you can

go further than that; you can see whether it is a man or woman, tall or short, covered up by the clothes or revealed by them. You have to interpret the clothes worn, the manners displayed, and wonder, "Can I imagine what a person is like who looks like X who has just walked into my room?" Could you ever have imagined that that person, who looks just like a man, existed? Or that that person who looks just like a man but has rouged cheeks, or is wearing sports clothes, could have existed? If you are frank, I think you have to admit you couldn't. The one thing that is really incredible is a fact. Conversely, when somebody comes into your room who looks just like anybody else, you still have to be able to retain your scepticism and say, "Could anybody who looks just like anybody else possibly exist?" You have to believe your senses and say, "Yes, apparently". The facts are incredible, but don't be beguiled into believing them because they are facts.

What do you believe, then? When you know what you believe, then you might think it useful to communicate it to somebody who isn't you. I can believe that it might be useful to try to communicate to people who are not me what I think psychoanalysis is, or how I should be a psychoanalyst. I don't know that it is really possible, but it *is* possible that other people might get an idea of how I do psychoanalysis if they are given a chance to find out. They don't necessarily have to rely on what I say is how I do it – they can form their own opinion. Even when you are not sure about this matter of soul and super-soul, a super-ego, an id, and an Atman, perhaps you can come to some architectonic, some idea of how you would describe the structure of the personality as a by-product of what you see when a person comes into your consulting-room and says, ostensibly quite truthfully, that they want an analysis. Speculative imagination, speculative reasoning – to put into pictorial terms, a new-born infant opening its eyes and staring at its mother. Imagine it or pictorialize it as you wish.

What next? What stage would succeed that of a speculation and imaginative reconstruction of this kind? Possibly reconstruction has something to do with it; possibly we do attempt to formulate a kind of architectonic, the building-up of a system of thought into a stable form. I can think of various versions of it, like Cantor's exploration of matrices. We are familiar with Freud's attempt to build up a system; we are also familiar with the fact that he felt that he had not completed his investigation, that his life was not prolonged sufficiently

for him to satisfy even himself that he had completed his system or what he was capable of. The problem has to be passed on, delegated to his survivors, the inheritance passes to others who might be called his professional family, his professional colleagues.

Recently even the mathematicians have considered theories like Heisenberg's Uncertainty Principle, the incompleteness theory; they indicate how the same awareness of incompleteness, uncertainty, has penetrated into things that have appeared to be so settled, so serviceable, such as mathematics, logic. Even a logical construction is criticized on logical grounds; this means that there is still some sort of logic but our understanding of logic has to extend – not that the logic is inadequate. This is what is happening with the Intuitionists – Brouwer, Heyting, etc.: they are investigating or proposing a mathematics that arouses a good deal of hostility on the part of the established mathematicians. In metapsychology Gödel's investigation, his theory about the Law of the Excluded Middle, also arouses curiosity. We could say that this exercise of curiosity, of speculation, extends even into the realms of speculation. To that extent we could say there is something that hitherto has not been revealed but has been sufficiently revealed to show the unknown even in psychoanalysis: the idea of there being *an* unconscious, as well as a *quality* of unconscious – things are unconscious, we have unconscious feelings and ideas.

It would be as well to consider an unconscious that has never been anything else, has never been conscious. I suspect that a clue to this is given by this theory of Melanie Klein's – projective identification. Even the foetus develops a capacity for what is later called projective identification. In other words, it has feelings or primordial ideas that it tries to deal with by evacuating them – a primitive mechanism derived maybe from the physical capacity for evacuation, literally, so that the amniotic fluid is polluted with meconium. I am suggesting that besides the conscious and unconscious states of mind, there can be another one. The nearest I can get to giving it a provisional title is the *inaccessible* state of mind. It may become inaccessible because the foetus gets rid of it as soon as it can. Whether it is an awareness of its heartbeat, or an awareness of feelings of terror, of sound, or of sight – the kind of sight experienced through the pressure on the optic pits by changes of pressure in the intra-uterine fluid – all that may never have been what we would call either conscious

or unconscious. It is difficult to contemplate because when we are contemplating it, we are in a conscious state of mind – like waking up and saying we had a dream. That is an elaboration in a state of mind appropriate to being what we call 'awake'. But the dream took place – if it was a dream – when we were asleep, and that is a quite different state of mind. So the conscious account of this event, these places we went to, these places we saw, is certainly erroneous. It is possibly rational – Freud claims that dreams are rational, that they can be given rational interpretations, which is perfectly true. But that is not of the dream itself. When someone who is wide awake has one of those experiences, we say that he is hallucinated or deluded; that state of mind has not been investigated because it is so much simpler to put that patient into a mental hospital or into an entirely different state of mind by the administration of drugs. And anyway it has to be investigated by somebody who is wide awake, fully conscious, and in possession of all his senses. When I say 'all his senses', I do not mean all of what my contemporaries and what rational and reasonable people call 'senses'; I include senses of which I myself may not be fully or particularly aware – the uncertainty principle, the incompleteness principle. So even the mathematicians cannot help me very much, because I think they themselves have reached a similar impasse in this problem of trying to elaborate what they call rigorous thought or rigorous thinking. I have already touched on this in talking about the fact that a state of rhapsody and expressions of rhapsodic excitement aren't good enough; we do need some sort of discipline, rigour of thought. I haven't said what kind of rigour; I don't think I could. Someday, perhaps now, somebody will be able to. But they have first of all to be acquainted with, and able to recognize, a state of mind that is not adequate. There is not much room for dogmatism or bigotry; that has gone too far; that seems to me to cross the point of no recall. Somebody who is that amount disciplined, or that amount rigorous, or that amount bigoted, is not within reach of the realms about which we need to know more.

Since we are now embarking on a somewhat different theme, we would do well to consider what that theme is. It has a great deal to do with this matter of judgement because by this time we have a lot of information available on which to operate. If we consider for a moment what we gather, what we have the intelligence to be able

to gather, how are we to have the wisdom to know which part of this gathered information is worthy of further consideration at the *present time*? What is to put all this material into order – in order of precedence? Who or what chooses or decides or acts as the authority in the person? It may be possible that the matter could be illuminated to some extent by observing . . . [*tape ends*].

COGITATIONS

1958–1979

Cogitations, edited by Francesca Bion, was first published in 1992 by Karnac Books, London. A new extended edition was published by Karnac Books in 1994.

EDITOR'S INTRODUCTION

Cogitations is the name Bion gave to the occasional short notes he had begun to write in the February of 1958 in order to clarify his thinking about the difficulties of working with psychotic patients using an unmodified psychoanalytic method – work informed by and shared with his two closest colleagues (who, like Bion, were in analysis with Melanie Klein), Hanna Segal and Herbert Rosenfeld. That clinical work formed the foundation of the clinical papers reproduced in *Second Thoughts* and the formulations in the four books of the 1960s: *Learning from Experience*, *Elements of Psycho-Analysis*, *Transformations*, and *Attention and Interpretation*.

The notes cover the period before, during and after the production of those books and papers; they show in detail the evolution of his ideas and theories, and, as both André Green (in his review of *Cogitations*, which is included in this volume) and Francesca Bion have written, they clarify many of the obscurities in the books created by Bion's antipathy for supplying his preparatory and linking apparatus, which would have gone some way to providing bridges for his readers.

Cogitations comprises notes, edited by Francesca Bion, made between February 1958 and April 1979.[1] Notes that contained references to patients were omitted, although on later reading it seems clear that at least some of them might have been published with some disguising alterations. Some notes were judged to have been too personal to include. The 1994 extended version of *Cogitations* was compiled from Bion's notes together with the appended short report from 1967, 'Notes on Memory and Desire' (see Volume VI).

[1]The notes between November 1973 and April 1979 include transcriptions from tape-recorded notes.

Bion's notes – some short and epigrammatic, others extended over several pages – are an invaluable aid to understanding those of his ideas for which he had omitted many of the intermediate links in his thinking. As André Green has expressed it in his review, "the author's formulations are less condensed and . . . he makes us witnesses to the process of the unfolding of his thought. We literally follow him." These original notes have been augmented by the inclusion in *The Complete Works* of a set of more recently unearthed notes, published in Volume XV as 'Further Cogitations'.

In an undated note (but clearly from 1960) entitled 'Communication', Bion writes:

> Language has been invented; translation can be achieved; musical and mathematical notations exist; men compose and paint. And now psychoanalysis attempts to elucidate the barriers and links that hinder or promote the relationships that require a capacity for communication. Nevertheless, the success of psychoanalysis lies so far not so much in bringing communication nearer, as in showing unmistakably the feebleness of our methods of communication even in the communication of disagreement. But this does not touch a yet graver issue, namely the problem of communication with our successors, for it would appear on the surface that if we cannot communicate with our contemporaries, we are even less likely to be able to communicate with our successors. If this communication cannot be made, the future development of analysis is imperilled and the successful discoveries made so far could be lost to the world. [p. 168. this volume]

In this urge to put into writing his half-sketched thoughts, as well as his more complete formulations – for his own purposes – Bion was using communication in the service of preserving the links in his *own* mind. In *Cogitations* we find many of those which had been present in his thinking but omitted from the books and journal papers of the 1960s and 1970s. It bears a resemblance to the relationship between a discovery of half-finished sketches by a painter, and their better-known, completed oil paintings with which we might be familiar from galleries.

Cogitations

Thought is only a flash between two long nights,
but this flash is everything.

Henri Poincaré

FOREWORD

'Cogitations' was the name Bion gave to his thoughts transferred to paper. The physical act of writing was, he found, an aid to his thinking – typing would have been too noisy and 'fidgety'. He wrote slowly, neatly, with very few alterations, on loose sheets, most of which he subsequently fastened together in two lots (unfortunately not in chronological order). Many are undated, but I believe that the order in which I have arranged them is not grossly in error. They cover the period from February 1958 to April 1979. In addition to relating the subject matter to his published papers and books, I have applied some Holmesian detective work to variations in the colour of ink and paper, and to the style of handwriting, which he changed from time to time as he tried to improve his hand.

These occasional writings were his attempt to discipline, clarify, and evaluate complex ideas – both his own and those of others – by setting them out visually and by often addressing them to an imaginary audience. He never re-read them, but he must have thought them worth preserving because they escaped consignment to the waste-paper basket during gleeful paper-tearing sessions, especially before leaving Los Angeles in 1979. They will be of particular interest to those already familiar with Bion's work as an illustration of his doubts, his arguments with himself, and of how his initial ideas developed. They should not be read in isolation by newcomers, but as an adjunct to his published works, especially those of the 1960s.

The compilation of this book affirms my belief that it forms an essential part of Bion's work and that it would be a considerable loss to psychoanalysis if its contents were to remain imprisoned in filing cabinets.

February 1958

Psychotic mechanisms

At last I think I see daylight on a point that has baffled me for a long time: what does the psychotic patient think analysis is? Partly an activity that is followed by consequences such as those that attend on events in the realm of physical fact; partly a mental event in which consequences (as they exist in the world of physical reality) do not exist – there are only sequences. In a dream an act *appears* to have consequences; it has only sequences. What is needed is a spatial model to represent a dream. The verbal description would then be seen as an artefact in which certain elements, in an agglomeration that has no time component and no events that are consequent on other events, are highlighted by the imposition on them of causality and temporality. The capacity to impose on these elements both causality and temporality depends on the existence of a non-psychotic personality. This non-psychotic personality must be capable of (a) frustration, and hence awareness of temporality, (b) guilt and depression, and hence an ability to contemplate causality (since contemplating causes involves the possibility of having to contemplate one's own responsibility for certain events in the chain of causes). The capacity for verbalization is, as I have shown already, itself a function of the depressive position [*see* 'Notes on the Theory of Schizophrenia', read at the Eighteenth International Psychoanalytical Association Congress in London, 1953 (*see* Volume VI, pp. 73–84)].

One result is that verbal reporting of a dream is only possible when enough work has been done for the patient to be able to tolerate temporality and causality, i.e. frustration and guilt-depression, and the patient is therefore able to produce the artefact we call 'a dream' from the 'agglomeration' of mental urine and faeces [*see* 'Attacks on Linking', Volume VI, pp. 142–145].

10 January 1959

Scientific method

The patient said he couldn't find a pot to harmonize all the things in his studio. This would be a vagina or womb; an object like that sought by Poincaré [*Science and Method*, p. 30] which

> must unite elements long since known, but till then scattered and seemingly foreign to each other, and suddenly introduce order where the appearance of disorder reigned. Then it enables us to see at a glance each of those elements in the place it occupies in the whole. Not only is the new fact valuable on its own account, but it alone gives a value to the old facts it unites. Our mind is frail as our senses are; it would lose itself in the complexity of the world if that complexity were not harmonious; like the short-sighted, it would only see the details, and would be obliged to forget each of these details before examining the next, because it would be incapable of taking in the whole.

He adds the opinion that "the only facts worthy of our attention are those that introduce order into this complexity and so make it accessible to us".

How can something people 'feel' be measured? By postulating temperature after ridding oneself of prejudice of pairs of opposites. Then it is found that things, inanimate objects, are sensitive to temperature though they do not feel 'heat and cold'. What about love and hate? Are they not 'prejudices'? Should it not simply be 'x' – the amount of x, like the amount of temperature? Then one might be able to measure x even if one cannot measure love and hate, or heat and cold.

Braithwaite talks about scientific deductive systems in his *Scientific Explanation*. He says, "A scientific system consists of a set of hypotheses which form a deductive system; that is, which is arranged in such a way that from some of the hypotheses as premises all the other hypotheses logically follow." These are arranged in an order of levels such that the hypotheses at the highest level are those that occur *only as premises* in the system. Those at the lowest

level occur only as conclusions in the system. Those at intermediate levels occur as conclusions of deductions from higher-level hypotheses, and serve as premises for deductions to lower-level hypotheses [p. 12]. He gives as an example the deductive system associated with the theory of falling bodies. He then says that in most deductive systems each deduction requires more than one premise, but that in his example just given there is only one higher-level hypothesis, used as a premise, from which deductions to lower-level hypotheses are made. But is this really true? Implicit in it are many hypotheses thus: "Every body near the earth, freely falling towards the earth, falls with an acceleration of thirty-two feet per second per second". Surely in this is brought together in the one sentence a hypothesis about bodies near the earth, about bodies falling freely, about bodies falling towards the earth (unlike, for example, a rocket going into the sun's orbit), about distance, and about time.

All this is reminiscent of Bradley on causation [*The Principles of Logic*, Vol. I, p. 211]. Is a hypothesis the meeting of mental events which, in a moment of union, begin a process that issues in the change we call the depressive position? Bradley says,

> We should do better to call the cause the meeting of elements which, in the moment of their union, begin a process which issues in the change we call the effect.

He continues,

> An actual union of actual elements is the cause. Each element by itself and apart from this union is not even a condition. It becomes a condition when you place it ideally in union with others. But in order to do that you must make it an idea. In its character of condition it must so far cease to be fact.

This sounds as if there is a factual situation of multiple causes, a unification in a moment of time, leading to a change that issues in the effect *and* an ideational situation in which the 'elements' need to be made into 'ideas' via symbol formation, so that the ideas can be unified at a moment that then issues in a change we feel as the effect. It is not possible to do this if you cannot tolerate depression, because this ideational counterpart (the same as the 'scientific deductive system'?) is the process Melanie Klein calls the synthesis of the depressive position. And this would mean that the breakdown in symbol formation

is the inability to transform an actual union of actual elements into an abstraction, i.e. a scientific deductive system or calculus.

But it is probably necessary to make a distinction between two related processes. Assuming the factual situation of multiple causes (of which Bradley speaks and which I shall later regard as being none other than the elements common to all scientific disciplines, the elements that are also the feature of the paranoid-schizoid position and are synthesized in the depressive position) that have to be transformed into 'ideas' so that they then become part of an ideational system, it is evident that it would be useful to know how this transformation is brought about.

One can regard it psychologically as a process of hypothesis formation; that is to say, elements that appear to be constantly conjoined are implicitly stated to be so by being associated with a word, the word itself then having some of the characteristics of a hypothesis that states that such-and-such experiences and an external event in the world of fact are constantly conjoined.

But for our purposes we need to consider how the ideational system develops into the scientific deductive system. The ideational system I shall regard as relatively primitive and belonging principally to the mental dynamics by which ideas, related to objects, are formed. The scientific deductive system I regard as more sophisticated and related to permanent establishment of knowledge, or to the establishment of knowledge in a form that is permanent and indestructible.

The problem may be most easily broached (though not necessarily most accurately in the sense of being most closely approximated to the facts of development) by considering the groups of senses as the route by which awareness of external fact is acquired. I group them thus: (a) touch and smell, (b) sound, (c) sight.

Group (a) is essentially non-verbal, comprises all elements of what is later called sexual, and is expressed best by sexual acts and various peripheral manifestations of sexual acts. These peripheral acts often have the characteristics of (b) and (c) but are in essence sexual acts, and only (b) and (c) in outward appearance. Thus words are employed in love-making but are then actions and not conveyors of ideas except incidentally. This is made obvious in certain analytic situations, particularly in the analysis of the psychoses, where the patient clearly reacts to words as if he had experienced a sexual

approach by the analyst. Group (b) is verbal and musical, but the verbal characteristics that are relevant are not those of content so much as those that are related to the establishment of patterns of sound. Group (c) is essentially verbal and pictorial, or ideogrammatic.

What does the psychoanalyst do? He observes a mass of "elements long since known but" – till he gives his interpretation – "scattered and seemingly foreign to each other". If he can tolerate the depressive position, he can give this interpretation; the interpretation itself is one of those "only facts worthy of our attention" which, according to Poincaré, "introduce order into this complexity and so make it accessible to us". The patient is in this way helped to find, through the analyst's ability to select, one of these unifying facts.

The fact that I here equate with what Bradley calls "the actual element" is in a sense in no way different from the facts or actual elements that are the objects of curiosity, elucidation, and study in any science whatever, although this fact may be obscured because it is a 'fact' or 'actual element' of the kind that the analyst is inviting the patient to study – namely, the patient's own.

It will be observed that in the theory I am putting forward I am postulating a phenomenon with three facets:

1. what Bradley would call 'actual elements in an actual union', which is identical with what the scientist would call 'observable data' in a relationship with each other that is equally observable,
2. an ideational counterpart of the above, which is dependent upon the individual's ability to translate an 'actual element' into an idea. (The psychotic fails to do this, and even when he verbalizes still thinks that words are things.) This operation depends on the individual's capacity to tolerate the depression of the depressive position and therefore to achieve symbol formation. This phase is identical with the scientist's ability to produce a scientific deductive system and the representation of this, which is called calculus [Braithwaite, 1955, p. 23],
3. a mental development that is associated with an ability 'to see facts as they really are' [Samuel Johnson to Bennet Langton, *see* p. 112, this volume, for details] and internally with a sense of well-being that has an instantaneous ephemeral effect and a lasting sense of permanently increased mental stability.

The peculiarity that distinguishes the psychoanalyst from his analysand is that the analyst is able to select the worthwhile fact, produce the deductive system and its associated calculus, experience the moment of union when the elements meet to give rise to a feeling that the cause has been found, and begin a process that issues in a change that produces a feeling that an effect and its cause have been linked [Poincaré, 1914, on defect of logic, p. 126; Braithwaite, 1955, p. 24].

The analysand, on the other hand, is made aware of an hypothesis in a deductive system which he may or may not be able to use as a premise for further deductions. The deductive system thus formed may enable him in his turn to select one of these unifying facts of which Poincaré speaks.

At this point it is necessary to review what I have already said from a somewhat different angle: if we are to assume, with Bradley, that there are elements in actuality that come together at an actual moment to initiate the process of change that leads to what we call the effect, those elements and that moment must be determined ideationally by the selective process through which, according to Poincaré, the individual picks on 'worthwhile facts'. I would therefore suggest that in the description of elements in actuality of which Bradley speaks, he is not really accurate in supposing that they unite at an actual moment to produce an actual process of change that issues in an actual event. Rather, it is true to say that in actuality a stream of elements exists, some of which are *seen* to unite at a moment that, like the elements themselves, is selected *by the predisposition of the observer* and are seen to issue in a process of change and its attendant effect – events that are a peculiarity of the observer's outlook. I suggest then that the stream of elements remains constant in actuality, but the union of those elements and the choice of the elements that are supposed to unite, together with the choice of the moment at which the union is supposed to be effected, depends upon the observer and in particular on what we should call the observer's disposition (if we are analysts) or scientific discipline. If a steel ball drops on a marble floor, the elements that are seen to unite at a particular moment to initiate the process of change will differ if the observers are, say, a physicist, an astronomer, or a philosopher addicted to Berkeley's new theory of vision.

The question that arises now is this: how far is the scientific outlook, the attempt to understand, a compromise between the

necessity, imposed by the compulsion to survive the 'reality principle', of knowing the facts of external reality, and the necessity, imposed by the psyche's intolerance of the paranoid-schizoid position or the depressive position, to move freely from one position to the other and back without depressively coloured persecutory feelings on the one hand, and depressive feelings untinged with feelings of persecution on the other?

The quotations on scientific method which I have cited from Poincaré and on causation from Bradley are open to the objection that they are expressions of the inner tensions of the personalities of their authors, and in view of the subject matter of this paper cannot be taken as valid descriptions of scientific method. Since it is my object to show that scientific method itself lacks the 'objectivity' that is widely attributed to it, and may indeed spring from very deep-seated elements in the personality which seek fulfilment, it is obvious that the very thesis of this paper may be taken as a refutation of its premises.

To this I can only reply that I am aware of the objection and have therefore devoted considerable thought to using only such descriptions of scientific method as appear to me to be unsurpassed for clarity of expression and the authority that their writers may be held to have as exponents of scientific thought. I have carefully excluded quotations that display illogicalities or evidence of any weakness that would invite criticism on scientific grounds by those accustomed to scientific method.

It is commonly held that the function of a science is to establish general laws covering the behaviour of empirical events or objects in such a way that it becomes possible to make reliable predictions of events as yet unknown [Braithwaite, *Scientific Explanation*, p. 1]. Braithwaite points out that once a generalization is formulated that all whales are mammals, it enables us to predict that the next whale we meet will be a mammal. He goes on to hint, however, that many questions that science is expected to make answerable are historical, and in particular such questions as are directed to the elucidation of causation. Leaving aside for the time being the impingement of this aspect of the problem on the discussions by physicists and philosophers, I wish to emphasize the fact that the historical question may be regarded as the reciprocal of prediction in that the function of the scientific generalization is to make it possible to summarize past

experience in such a way that when, as it were, a whale turns out *not* to be a mammal, it will at once become clear either that an error has been made in the original formulation of the hypothesis, or is about to be made. It follows that the scientific law is closely related to, and an epitome of, experience; that it has relationships with memory, and that a capacity for the formulation of scientific generalization must be an essential function of any personality if it is to be capable of learning by experience (i.e. storing experience in an epitome and comparing a fact with the expectation engendered by the 'law'). In essence those postulates remain true even when we deal, as analysts, with primitive and rudimentary manifestations of this capacity far removed from the sophisticated demonstrations of the capacity evident in the best work, say, of modern physicists.

Most of Braithwaite's introductory discussion of what can be considered as legitimate material for scientific study – as data on which scientific law can properly be formulated – shows that what is at issue is really a matter of choice. He himself makes the choice when he says that he concerns himself with "the relationship of public scientific laws to public facts of observations" [*Scientific Explanation*, p. 6] and eschews consideration of the problems involved in the transition from private knowledge, as the phenomenalist would regard it, "to public knowledge of the material objects of common sense". Whatever choice is made, it is to be expected that it brings its own problems with it, and this point is well understood by the student of scientific method. What is not so easily appreciated is the immediacy of the impingement of the problems with which the philosopher of science is familiar on the mental phenomena that modern psychoanalytic methods make overt. Braithwaite's decision so to limit his field as to exclude the problems that confront the philosopher of perception [p. 6] involves using "the observations which form the basis of scientific laws as being observations (as common sense understands the word) of material objects and their properties" [p. 7]. This at once raises the question, what is common sense? – a problem that has received inadequate attention because without modern psychoanalytic technique and theory it is not possible to make any useful approach to the question, or perhaps even to realize that a most significant phenomenon lies embedded in the term, which is itself a striking emanation of common sense.

Let us approach it clinically: a patient enters the consulting room, notices that the couch is in some disorder but, making only a minor adjustment, lies on it and proceeds with his associations. In due course evidence from his associations indicates that at this particular juncture, and taken with sundry other facts not germane to this discussion, he is experiencing an increase in anxiety and, furthermore, that the anxiety has as its ideational content the disordered couch as part of the furniture of a scene of parental intercourse. This conclusion, and the interpretation that is the psychoanalytic act by which it is expressed, is arrived at on the basis of observed facts seen in the light of a psychoanalytic hypothesis. But common sense tells this patient that he is lying on an ordinary couch and that ordinary people, as he himself might say, would know that that is what it is and that its disorder was due to the movements of the previous patient upon it.

To prevent too minute a discussion, I propose that we may now say that common sense is a term commonly employed to cover experiences in which the speaker feels that his contemporaries, individuals whom he knows, would without hesitation hold the view he has put forward in common with each other. Common sense, the highest common factor of sense, so to speak, would support his view of what the senses convey. Furthermore, he has a feeling of certitude, of confidence, associated with a belief that all his senses are in harmony and support each on the evidence of the rest. In this sense also, private to the individual himself, the term, 'common sense', is felt to be an adequate description covering an experience felt to be supported by all the senses without disharmony. As contrast, I may cite the experience in which a tactile impression of, say, fur – sudden and unpredicted – gives rise to the idea of an animal, which then has to be confirmed or refuted visually; and so, it is hoped, the common-sense view is achieved.

But there is a difficulty. So far one might say that the patient's view is essentially at one with the strictly scientific view that Braithwaite investigates after limiting the scope of his survey in the way I have shown above. The analyst, however, is also able to claim that his interpretation is based on common sense; but it is common only to some psychoanalysts who may be presumed to witness the same events and make the same deductions.

The analyst's problem is not associated with the objection that the phenomenologist might raise, although it can be argued that an awareness of the phenomenological philosopher's criticism of scientific theory is implicitly supported by the analyst's view that all analysts should be psychoanalysed. The phenomenological philosopher's objection is obviously not met by the psychoanalyst's procedure, and for the time being we shall discuss this problem by relegating it to the sphere concerned with the transformation of private knowledge to public knowledge.

The serious problem can be emphasized if I maintain that the hypothesis on which I base my interpretation is itself an embodiment of common sense in the sense in which I have already described the term. The hypothesis purports to be a generalization from 'common sensations' applicable on an occasion when there arise again 'common sensations' that appear to lend themselves to generalization in the same hypothesis.

It may be argued, and in fact is argued, that these are not common sensations and that the generalizations from them cannot be attributed to the dictates of common sense. As Hanson[1] has pointed out, such an argument levelled at a physicist who says he is measuring a wave length justifies the demand that the questioner should be acquainted with the discipline of electricity and magnetism as it is investigated by the techniques of modern physics. These techniques may be said to have two components. The first is dependent on mechanical aids that multiply the number of sensory perceptions. (I exclude considerations of what appear to be transformations but are not, such as when an impression of weight is conferred not by direct imposition on the hand but by the visual image presented by the pointer of a scale.) This multiplication of sensory experiences provides a field in which common sense can operate to determine what is the 'common sense' of the available sensory experiences now they have been augmented. Clearly I am attributing a very important position to whatever it is in the psyche that is ordinarily called common sense whose function it is to determine the 'common sense' of the sensory experiences. Furthermore, it may seem that a certain minimum of sense experiences is necessary before it can be reasonably

[1][See N. R. Hanson, *Patterns of Discovery* (1958) and 'Notes toward a Logic of Discovery' (1965). *Ed.*]

said that common sense can determine what is the sense that is common to all of them. This is a folklore version of the sophisticated scientist's need to establish adequate correlations (cf. A. D. Ritchie on the inadequacy of 'the far-off stars are redder' as a basis for the red shift and the expanding universe). [*Studies in the History and Methods of the Sciences*, 1958, p. 215.]

The second component is dependent on the mental equipment of the observer. The philosopher of science concerns himself, as is already apparent from the brief survey I have made of Braithwaite's demarcation of the area that he wishes to discuss, with a limited aspect of the observer's mental equipment. Even the phenomenological philosopher of scientific method intends to restrict his field, though it is doubtful whether he means to restrict it so severely as in fact it is – thanks to the lack of the psychoanalytic discoveries that could have given greater freedom. The psychoanalyst, as is to be expected, excludes no part of the mental equipment from his survey except in so far as his knowledge and capacity by their own limitations forbid automatically the fullness of inquiry he would desire. His investigation of scientific technique has been imposed on him first by Freud's impulsion to investigate the human mind scientifically, and second by Freud's realization that his discoveries compelled suspicions of the mental equipment of the investigator – Freud himself in the first instance.

The exigencies of psychoanalytic history have forced this investigation into a somewhat limited channel: the scientists investigated are predominantly psychoanalysts, which means that their grasp of methodology may be rudimentary in the extreme and lacking in even the elementary sophistication that could be expected, say, of a physicist who came for analysis. The weight of the investigation has perforce been directed to elucidation of what we now regard as the psychopathology of the psycho-neuroses. These limitations are, however, not as great as might be supposed, and are certainly not, in my opinion, as great as my own description makes them appear to be. For this reason I am persuaded that much psychoanalytic work done has been an investigation of the scientific technique or mental component, but not under that name. One has only to consider Freud's theory of the reality principle and its dominance to appreciate that he is describing a development that must include in its more sophisticated manifestations the elaboration of what we now call scientific

techniques of – or techniques known to science as – deduction, induction, hypothesis, etc.

Although I expressly disclaim anything new in what I have to say here – precisely because in my view psychoanalysis has all along concerned itself with and elucidated these problems – yet I believe that there may be something novel in the juxtaposition of the facts which will serve to focus psychoanalytic attention more directly and purposively on elements that have still not been sufficiently regarded.

This brings me to the difficulty that I have had to approach through this long digression. The individual whose development has allowed the establishment of the reality principle to take place has established – with varying degrees of sophistication – a vast mass of hypotheses in the course of his life. Most of these have some degree of justification both in the external circumstances of the period in which the formulation occurred, and in the quality and degree of mental equipment available to the individual at the time. In other words, we do not need to assume that they were unjustified, although, as with the case I have mentioned, the patient is not slow to say that the *analyst's* reconstruction of what he believes to be the patient's original but still current hypothetical formulation is unjustified. So it is – on the level of mind on which the patient is at his most adult, most sophisticated, most scientific.

I shall return later to further discussion of common sense, but for the present I propose to leave this subject to carry further our investigation of the scientific hypothesis.

Braithwaite favours the view that the scientific hypothesis consists of a generalization and nothing else. He admits that Hume's formulation of the theory of constant conjunction is open to grave criticism and that it has done much to obscure the value of the view that he (Braithwaite) puts forward, though with important modifications. In particular he stresses the close connection that exists between Hume's view of constant conjunction, and Hume's view that there is no element beyond a generalization in a scientific hypothesis except a psychological fact about the association of ideas or beliefs in the mind of the person believing the law. It is evident to Braithwaite that there is a desire to find something in a hypothesis which goes beyond a generalization abstracted from facts observed by common sense, whether aided by mechanical apparatus or not. As an instance he cites the desire to believe that a scientific law asserts, in addition to

the generalization, that there exists some kind of relationship between the facts about which the generalization is made which is analogous to the logical relation holding between premise and conclusion in a deductive inference. Further instances of this tendency, cited by him, are the desire to believe in the existence of a relation of activity analogous to that occurring in volition or, finally, a quite specific relation not analogous to anything else.

To a psychoanalyst it is clear that the demands that could be made on any scientific law are endless and need be by no means be restricted to the few Braithwaite mentions [in *Scientific Explanation*, p. 10]. The point to which I would draw attention is the scientist's view that the scientific hypothesis is a generalization abstracted from the fact that certain facts have been found to be constantly conjoined – the constant conjunction theory. The complication is that clinical experience shows how strong is the desire to formulate a hypothesis that will state that certain events are constantly conjoined and that therefore we must regard the relationship to the facts from which it is supposed to be educed as a generalization, as being two-way; that is to say that the hypothesis may be regarded as (a) educed from constantly conjoined facts, and (b) designed, however it may be derived, to affirm that certain facts are constantly conjoined. It will be observed that the latter view is quite compatible with the former – incompatibility of the two views is not the point. But, assuming both views are correct, we may say that the scientific hypothesis fulfils the following three functions:

First, a private experience is transmuted into a public communication (whether it is in fact made public or not).

Second, the types of certain experiences, facts, or events are stated to be agglomerated, articulated, or integrated in time (past, present or future), the hypothesis being thus associated with memory and prediction. This function is intrinsically related to reality and cannot without deliberation be divorced from reality testing, that is, experiment and practical application; e.g. 'red sky at night, shepherd's delight' has to be tested out if it is to retain its vitality, even if the testing jeopardizes its existence.

Third, the mental bringing together of mental elements corresponding to Bradley's "meeting of elements which, in the moment of union, begin a process that issues in the change we call the

> effect" (I refer, of course, not to any supposed meeting of elements in external reality, but to the ideational counterpart of such an event; my comparison is between this ideational counterpart and the hypothesis as the ideational counterpart of the particular events to which the deductive system may be applied), and the selection of certain mental elements analogous to those mathematician's facts that, in the words of Poincaré, "unite elements long since known but till then scattered and seemingly foreign to each other", so that we can see each element in the place it occupies in the whole.

It will be appreciated that in the whole of this discussion of the nature of the scientific deductive system, the hypothesis embedded in its framework, and the calculus which is its representational counterpart, I have accepted as scientifically sound the idea that common sense may be, and should be, accepted as the arbiter that decides what are the facts in external reality to which these mental activities relate. The philosopher of science has always been brought to a standstill at this point, caught between the logic of the idealist philosopher on the one hand, and the feeling of unreality to which an acceptance of such logic would expose him on the other. There is essentially no difference between the reactions of Braithwaite and Doctor Johnson to the demands of the idealist.

It is possible that the scientist's dilemma, and therefore our own, may be seen differently if we now return to clinical psychoanalysis for the light it may throw on common sense and on that particular instance of scientific hypothesis and deduction known to us as a psychoanalytic interpretation.

Description 1 (D.1). Let us consider the following episode taken from the analysis of a psychotic patient. The patient, who is used to lying on the couch, looks apprehensively and cautiously about him, finally seating himself precariously on the very edge of the couch. His survey is perfunctory, as if confirming some preconception; his expression changes to one of dejection. After some minutes he has become established in his posture; he does not move, he does not talk, he is no longer apparently even anxious – just dejected. I draw his attention to his behaviour and to my presence, of which he seems to be only vaguely aware, by saying, "You are not lying down today".

He replies, looking at the couch, "There is blood everywhere". His tone implies distaste, and his reply carries the suggestion that it is the presence of blood everywhere that makes him unwilling to lie down.

I maintain that the description I have given is a common-sense one; I am not in two minds about any of the statements I have made, and I believe that any ordinary human being of my acquaintance would agree that the account is an accurate description, even when I employ terms such as, 'as if confirming some preconception'. Such a phrase is sanctioned by usage and may be expected to convey an impression with which the reader could match his own. Unfortunately, in this instance the reader can have no impression of the episode of which I speak other than that conveyed by me. But he can have impressions of what he may regard as similar experiences of his own. It therefore seems fair to say that I have given him an opportunity for the exercise of his common sense so that he can decide for himself whether or not his common sense tells him that an event such as I describe actually took place or not. In short, I am saying that it is common sense to say and believe that the facts were what I said they were.

To begin with I propose to maintain, with Braithwaite, that it is legitimate for my present purposes to ignore the problems that are associated with the phenomenological scientific philosopher's outlook, and to consider as facts those events that my common sense tells me are facts. The justification for this lies in the experience of scientists that it is conducive to a growth of knowledge to behave as if events that common sense says are facts provide adequate material for the formation of contingent propositions on the one hand, and objective tests of a hypothesis on the other. There is also a historical justification in such a procedure, for common-sense synthesis has always been the precursor of a scientific ordering in a scientific system. I repeat, therefore, that common sense declares that the facts are as I have stated them and thereby provide a basis for scientific work.

From this premise I select the possible trains of thought that I might pursue: one touches the nature of the common sense to which I appeal and to which, in conformity with the views of a powerful school of philosophers to which I adhere, I accord an extremely important role. For the time being I shall leave this thought in abeyance, merely contenting myself with a partial limitation of the term to cover that aspect of the personality which is a compact of a component of the senses, common to two or more of the senses, and which in

my belief has a social component analogous to that which Freud supposed might be the case with the sexual impulses, and which appears to me to be true of all emotional drives [Freud, 'Instincts and Their Vicissitudes', 1915c]. This train of thought I leave for discussion later.

The second train of thought following my premise that I have made a common-sense observation leads me to put two questions. Where is the patient's common sense? What has happened to it? I shall later consider the reciprocal of these questions starting from the point of view that the patient's description of the facts is the common-sense view, but for the present I consider only these two questions.

Description 2 (D.2). Is there any reason to doubt that the patient's judgement that there is blood everywhere is in his opinion a common-sense view? There are the following reasons for doubting it: he has shown in previous similar situations that he does not believe I share his view; the readiness with which he volunteered his explanation for not lying on the couch is an expression of confidence that I shall tolerate his opinion, not that I shall share it. He is even, at this advanced stage of the analysis, quite capable of making no response, because he knows that his view is not the 'common' sense one, and he prefers that the difference in outlook should not become public. He may be supposed, therefore, to feel that his sense of 'blood everywhere' is not common sense, is not in accord with the 'common' view demanded of him as a price of his membership of the group.

One answer to the question, 'Where is his common sense?' is therefore that it is where it always has been; it is still a part of that non-psychotic part of the personality which I believe, together with Mauritz Katan (1954) and other observers, always to remain in existence. None the less, the question still stands because from one point of view the patient does not behave as if he has any common sense or, if he has any, that it could be of any use to him. I am not, of course, suggesting that this is deducible from the one instance I have attempted to describe; it is a deduction from many similar episodes. Indeed, it is arguable that the patient has no conceivable interest in common sense, still less the question that I have put to myself about it. And yet the patient appears to feel that he has some identity of interest with me as the analyst, or he would not keep coming for analysis.

But now I think I see the answers to my two questions. Where is the patient's common sense? Obviously, it is 'everywhere'. What has

happened to it? Equally obviously, it has been turned into blood – 'blood everywhere'. If I am correct, then the patient and I are well on the way to establishing a 'common-sense' view, that is to say a view common to him and to me. But it is equally clear that my interpretation of the facts I mentioned in *D.1* involves me in having produced a new description, *D.2*. The description, *D.2*, of the facts owes its difference from *D.1* to the new hypothesis in the light of which I now regard the episode. I argued that I am entitled to regard *D.1* as common sense: I am prepared to argue that *D.2* has a sense common to me and my patient. But can I now maintain that *D.2* is a common-sense description in a wider, extra-analytic context, and if so, in what way?

Let us first turn to discuss the idea that *D.2* is a common-sense description in the limited field of that which is common to the patient and me. It is evident that even in this limited respect the interpretation of the patient's behaviour that I have proposed cannot, on the facts I have given so far, be regarded as a 'sense' common to the patient and myself. It is an idea selected or accepted in a penumbra of circumstances which suggest a resemblance to the new fact for which Poincaré says the mathematician seeks – "the link that unites facts which have a deep but hidden analogy" [*Science and Method*, p. 27]. For if it is indeed a fact that the blood which the patient describes as being everywhere is the transmuted common sense for which I am looking, then this fact does link a number of other facts in a way that demonstrates a deep but hidden analogy. Thus the patient, as I know, believes he is mad and has always felt himself to be unlike others, to have a feeling compatible with that of having no 'sense' felt in common with others, and no senses that appear to have a factor common to each other. This he often expresses (as do two other patients) in a reiterated plaint about almost any feeling he has – "I don't know why". I know that if he saw blood everywhere, and then also felt the blood everywhere, and furthermore thought he smelt it everywhere, then he would think he knew why – it would just be common sense to see blood everywhere because his common sense told him it was everywhere. Since, however, his common sense does not tell him so, it may be a matter of some interest and significance to consider *what* sense has told him so. *D.2* has thus served to point one possible direction for further inquiry, and at the same time to link the present fact, his statement about the blood, with previously observed facts touching his profound sense of isolation and uniqueness. I know,

furthermore, that this patient considers the sight of blood to be significant; it is felt to be something that has been lost, and the loss is felt to be associated with disaster for the object that has lost it. In the episode I have recounted, its presence was associated with feelings of depression and persecution (these last being observations of my common sense). I know the patient's hatred of reality is strongly coloured by the feeling that a sense of reality carries with it a stimulation of the socially polarized aspect of his emotional drives, and that this stimulation is felt to menace the ego-centric aspect of his emotional drives and therefore his narcissism, thus increasing his fear of annihilation. I know, therefore, that a belief that his common sense has been lost, destroyed or alienated is quite compatible with, and illuminant of, his previously expressed hatred of reality, or the mental apparatus that might link him with it.

It may be supposed that I am arguing that my interpretation is based on previous observations, that it is a scientific hypothesis in the sense that that term is used by those who consider a hypothesis to be a generalization from a number of particular observations of fact. But I no longer feel that this view is adequate, although it still seems to me to have substance. I do not wish to exclude from debate the influence exerted by numerous stimuli, subliminal or overt, which are received over a period of psychoanalytic experience. I think it would be misleading to suggest that the interpretation, *D.2*, owes nothing to the stream of stimuli which I, as analyst, have received. But I consider it to be equally misleading to say that *D.2* is 'based on experience'. Such a description should be reserved for beliefs, interpretations, hypotheses, which have demonstrably undergone what common sense would recognize as reality-testing. (Once more I appeal to common sense, that is to say a group or socially orientated sense whose 'purposes' go beyond the individual. I, as individual, need to consider what the 'group' will accept as reality-testing before I can feel that my view has the sanction of 'my' common sense.) I shall therefore suggest that *D.2* has, as one of the components to which it owes its emergence, the influence of external events on the analyst's psyche both in shaping the form the interpretation takes as a crystallization of experience, the memory component, and as a compendium facilitating prediction, and by virtue of that, reality-testing.

There remains the element whose existence was suspected by Hume and classified by him as 'psychological'. This element is most

obtrusive before the point at which the common-sense synthesis of experience becomes a scientific ordering in a scientific system. It is worth remarking at this point Braithwaite's comment:

> There is no hard and fast line at the point at which the common-sense synthesis of experience becomes a scientific ordering in a scientific system. Just as, in tracing back common-sense thought either in the individual or in the race, there is no point at which there were no generalizations believed, so in the history of a science there is rarely any one historical date at which it is possible to say that the first hypothesis was adumbrated. [*Scientific Explanation*, p. 28]

To this I would add that the same holds true of the history of an analysis – there is rarely a precise moment at which it can be said that a particular interpretation was first enunciated. Nevertheless, even though it is in fact difficult to say that a given moment is *the* moment, we may yet suppose such a moment to exist, and it is before this point is reached that the so-called psychological factors are suspected of playing a dominant role in the scientific activity. In other words, there is reason to look to the mentality of the analyst himself for the major contribution of elements in the totality of elements which issues in the interpretation *D.2*, namely that the patient feels his common sense not as an integral part of his personality but as blood, dangerous and persecuting, lying about him everywhere. Before Hume's insistence that there is nothing in a scientific hypothesis but a generalization – and that any added element does not belong to the scientific generalization properly speaking but is only the psychological factor in the observer which he recognized as a tendency in the human mind for certain ideas to be associated together – philosophers of science were not prepared to admit either that this something extra to the generalization did not exist, or that its existence lay in the personality of the human being. It was supposed that this something was analogous to the logic of the human mind. My view diverges from the view that the scientific hypothesis or law includes more than a generalization and that that something is a function of external reality. It approximates to the views of those epistemologists – Kant, Whewell, Mill, Peirce, Poincaré, Russell and Popper – who tend to the beliefs compatible with the idea that scientific knowledge is the result of the growth of common-sense knowledge. My agreements – and disagreements – with these epistemologists are a direct consequence of a psychoanalytic

investigation of the phenomena known to all of them under various synonyms for scientific common sense. It is my view that the impasse in which the scientists and philosophers of science find themselves is not capable of further adumbration, let alone resolution, without the employment of psychoanalytic research, and more precisely research into the phenomena collectively called common sense which are the main theme of this inquiry. I say the main theme, but in fact I propose to make it so only because its data, elusive though they are, are none the less more accessible to preliminary investigation than phenomena associated with intuition, the first hypothesis, the inspiration (Karl Popper, *The Logic of Scientific Discovery*, pp. 31, 32). If I do not elucidate this last, it will be because I cannot. In fact I do not consider that the elaboration of a deductive system from facts declared by common sense to be so, can be separated from the earlier phenomenon which is a precondition for the elaboration of a deductive system, namely the inspiration. I propose, therefore, to make no strenuous effort to separate the phenomena from each other.

I shall first consider the opposite of the hunch. "I don't know why", says the patient. "I don't understand", replies the patient to a particularly clear interpretation I have just given him. By 'particularly clear' I mean one that has, in my opinion, drawn together a number of apparently unrelated facts in a way that demonstrates their relationship, and does so in terms so precise that the expression of the interpretation does not vitiate the deduction that is intrinsically dependent on its mode of expression. These two statements, 'I don't know why', and, 'I don't understand', are as active, as affirmative as 'I know', or, 'I understand'. In effect my interpretation has said, 'This is why . . .', and, 'Listen to what I am telling you, and you will find I have made you understand . . .'. Both statements are implicit declarations by me that the relationship between the patient and myself is an analogue of the relationship that might exist between his capacity for inspiration, whatever that is, and the ideational counterpart of apparently unrelated elements scattered and apparently foreign to one another. I have in effect said, 'I know why . . .', i.e. I unite elements. The patient has in effect said, 'I, unlike you, do *not* know why . . .'. My point is that this statement is a declaration of equality with me; not simply rivalry, but equality of status. 'I unite . . .' is one statement. 'I disunite . . .' is the antiphonal reply. I propose to clarify my point in a series of formulas thus:

1. I unite ↔ I disunite;
2. I synthesize ↔ I analyse;
3. I metabolize ↔ I catabolize;
4. I analyse violently ↔ I split;
5. I synthesize violently ↔ I fuse.

Analysis and synthesis are both involved in understanding. If the act is carried out lovingly it leads to understanding; if carried out violently, i.e. violently with hate, then it leads to splitting and cruel juxtaposition or fusion.

16 May 1959

Common sense

On Friday X's anxiety was far more marked: he hated me, or felt I was not what he thought me; he was disillusioned; my practice had gone; I was ill or dying. But these disjointed scraps were at least *possible* interpretations about a real man; I could see that he *could* hold such a view about facts that *might* be observed by him. Why was this?

It was a kind of disjointed rage, a fragmented hatred, but said with fear. This is the importance of the father, and this is the importance of the mother. He can get inside her as a tank from which the father can be attacked. The patient retreats into a state of mind, e.g. insanity, from which he can launch his attacks.

Where then is his common sense? Why blood? Blood is not faeces. It is essential to his life – like common sense. It has become bad *outside* him; not turned to faces inside him, but bad and dangerous outside.

The blood – common sense – the semen in which he sits, is dangerous and bad. It is laughter, sexual laughter; noise, horns, drills, banging. It is all the bizarre objects. It is a kind of orgasm that cannot be contained within a disciplined framework. The disciplined framework is reason, mathematics, logic. The analyst becomes a very frightening, aggressive object who takes control of the genitalia so as to give effect to, to fulfil a violent oedipal assault of a murderous kind on the father *and* mother. "I am going to make you shoot your mother. Look what I've got! The penis and balls with which I shall make you shoot your mother!"

The violence seems to be related to a kind of greed in which no choice can be made because nothing can be discarded. This operates against any advance in analysis; no cure can take place because no infantile mechanism is to be given up. And nothing can be taken in because of the conflicting aim to take something else in. Cigars *and* breast milk, pap *and* caviar. Projective identification of food: asceticism and gormandizing.

Megalomania. A matter of having to *be* as well as *have* everything. Common sense produces, from this point of view, a restrictive state

of mind; it conflicts with megalomanic narcissism. Without common sense, phantasy can be felt as fact.

Indolence can be the need to remain free to indulge phantasy: again, common sense is the obstructing force.

Public-ation is an essential of scientific method, and this means that common sense plays a vital part. If it is inoperative for any reason, the individual in whom it is inoperative cannot publish, and unpublished work is unscientific work.

* * *

The individual analyst has two main contacts: his patients and society. In the first certainly, and in the second probably, he will have it brought home to him how little he knows and how poor his work is. In this respect his position is not unlike that of the soldier in war who is aware of his own troubles but not of his enemy's. It must therefore be borne in mind that the fundamental importance of our work demands that kind of fortitude and high morale which places the welfare of the analytic group and its work before the welfare of the individual analyst, and sometimes before the welfare even of a particular patient. This, taken in conjunction with the isolation in which analyst and patient work, means that the analyst must, in addition to the commonly recognized equipment, possess a social consciousness of a very high degree – common sense must never be allowed to become dimmed, even when work is concentrated on the more arcane and narcissistic attributes of the analyst's patients. In other words, when concentration is focused predominantly on psychotic mechanisms, the non-psychotic aspects of the work must be as present to the analyst's mind as his awareness of the nonpsychotic aspects of the psychotic patient's personality are in the analysis he is conducting. Or, to put it another way, the analyst must never cease, even in the midst of his analytic work, to be a member of one or more social groups.

12 July 1959

I am nonplussed yet excited, as if on some important trail I cannot get hold of. X is not random reconstruction: then what does he do? Could it be logically or mathematically described? If he is saying something apparently insignificant, he can produce coherent, recognizably coherent, speech. Then he may become vehement and speak emphatically. "Then we went down the road. It was" (persuasive and confidential) "just a quite ordinary road. And I said to him, "This won't do" (quietly emphatic and faintly reminiscent of the "I said it very loud and clear" verses of Lewis Carroll). I just made it obvious to him that it just *would not do*", the last three words spoken quietly but each one separately emphasized. Has it any meaning for me? And if it has, what is that meaning? And is the meaning it has of any importance except as an indication of my personality and how it reacts to a particular form of stimulus? Yes, obviously it has, because I have just spoken of a 'particular form of stimulus' and this at once suggests (a) it *is* a stimulus, and (b) it has a particular form.

14 July 1959

It is clear that if the search is for the harmonizing fact that marks the transition from the paranoid-schizoid to the depressive position (Poincaré, *Science and Method*, p. 30, and Braithwaite, *Scientific Explanation,* on causation), then much depends on the nature of the elements that are seen to be harmoniously coherent on the discovery of the harmonizing fact, and on the mental make-up of the investigator who discovers, or (according to Poincaré) selects the harmonizing fact. To a religious such a fact might well be quite different from that selected by a physicist. The fact or formula discovered by a mathematician would differ again. The reader of the works written by such pioneer discoverers would have an experience similar to the emotional experience of the discoverer; he would discover the discovery, or the book, or the sentence, or the phrase in which the selected fact was embodied. But – and here lies the central fact – in all these instances, as I have already shown, a series of facts out of an infinitely larger totality of facts is given coherence by the selected fact, and that is all; not only is *the fact* selected, but all the cohering facts also are a selection. Thus one fact is observed to 'explain' a great number of other facts, which facts may be considered to belong to the domain of Physics. But this is no more than saying that all the facts that are not given coherence by the selected or discovered fact are either unknown, ignored, or regarded as belonging to some other discipline or system. A result of this is that some kind of objective reality is attributed to the coherent system of facts, whereas there is no evidence to suppose that such a system, say physics, is anything more than an appearance artificially produced by the limitations of the human mind unable to do more than see a tiny fraction of the totality of facts, and prone to attribute to that fraction of facts a relationship intrinsic to itself, while the supposed relationship between the facts is only a relationship that each fact has to the capacities of the human observer.

This argument can be extended further by considering not physics but the whole of what we call a scientific outlook, the outlook and

methods common to all the sciences, as being a peculiarity of the human mind analogous to that peculiarity of human visual capacity which makes it sensitive to a comparatively small range of wavelengths.

The supposition that man's mathematical ability receives (from the apparently endless series of discoveries that have in the past two thousand years been associated with the application of mathematical techniques to physical and astronomical phenomena) some kind of title to be considered as itself an intrinsic objective quality in the universe it has helped to illuminate, can now be seen as open to question. It is arguable that it is simply a peculiarity of the human mind which tends to illuminate just those phenomena that lie within its powers of illumination, and so does not prove that the universe has mathematical qualities, any more than the eye's sensitivity to certain wavelengths proves that there is in the universe an objective essential quality which can be called 'visibility'.

* * *

The reason why a mathematical statement is given such importance by the scientist is that the deductions made from it appear to correspond with the parallel developments in the scientific deductive system which it represents, and in the corresponding world of empirical data. But this may merely mean that mathematical logic is the expression of the ultimate limits of human mental capacity – that an appearance of finality is observed in a mathematical statement of natural phenomena which in reality belongs to the inability of the human mind to go further, and not to the exhaustion of the natural phenomena under observation.

This is the reciprocal of my reply to Prichard (*Knowledge and Perception*). That is to say that just as it is idle to deny the title of 'knowledge' to what a human being knows because it is possible to imagine that another being might know more, so is it idle to suppose that because some mathematically precise behaviour appears to be observed, say in astronomical phenomena, this mathematically precise behaviour is any more than that aspect of the behaviour which we as human beings are capable of observing.

15 July 1959
(4.30 a.m. Blast it!)

X said . . . well, what? He used words in such a way that they seemed to indicate that his mother or relatives had cut off supplies; that he could sell out £500 of shares and go to the cottage, in which case there would only be £50 and that just could not buy food. "That's all there is to it." I attempted to draw attention to the fact that even while there was an opportunity for analysis, he could make no use of it. He defends by taking this as an accusation in which he is to blame and thus denies the existence of a very bad obstructive object. The rational comes in, therefore, not as the product of an elucidation, but as a defence against the elucidation. If I put to him that his mother is a very dangerous object denying him food, then I am giving him material to defend himself against the common sense view, and am myself felt to be disturbed to an extent which makes me unable to see the common-sense view.

There is something curious about this kind of defence which is analogous to an interpretation in which the elements are so ordered that the narcissism of the patient is spared. But I have already said that narcissism, apparently primary narcissism [Freud, 'Instincts and Their Vicissitudes', 1915c], is related to the fact that common sense is a function of the patient's relationship to his group, and in his relationship with the group the individual's welfare is secondary to the survival of the group. Darwin's theory of the survival of the fittest needs to be replaced by a theory of the survival of the fittest to survive in a group – as far as the survival of the individual is concerned. That is, he must be possessed with a high degree of common sense: (1) an ability to see what everyone else sees when subjected to the same stimulus, (2) an ability to believe in survival of the dead after death in a sort of Heaven or Valhalla or what-not, (3) an ability to hallucinate or manipulate facts so as to produce material for a delusion that there exists an inexhaustible fund of love in the group for himself. If for some reason the patient lacks these, or some similar series of capacities for attaining subordination to the group, he has to defend himself

against his fear of the group – which is known to be indifferent to his fate as an *individual* – by destroying his common sense or sense of group pressures on himself as an individual, as the only method by which he can preserve his narcissism. In the extreme form of defence in the psychotic the result of these destructive attacks appears as a superabundance of primary narcissism. But this is an *appearance* – the supposedly primary narcissism must be recognized as secondary to a fear of 'social-ism'.

This digression brings me back to the psychotic defence against interpretation which I said was analogous to the analyst's attempt to evade any conveyance by the interpretation of an element which constitutes, or is felt to constitute, an attack on the patient's narcissism. In practice this means evading the elucidation of illusory, delusory, or hallucinatory mechanisms for making the patient feel loved, lest such elucidation should show him that such love as he wishes to feel that he receives does not in fact exist. This in turn means that he analyst has to convey by various means that he loves the patient, and that in this respect he is a representative of the common sense of the patient's social group which loves the patient more than it loves itself. This latter belief can of course be supported by the patient by his believing that analysis itself is an expression of such group love for him. Or, in early infant terms, that the breast is a gift to him from the family group.

In so far as the patient is successful in evading the attacks on his narcissism, he experiences a hallucinatory gratification of his craving for love. This, like all hallucinatory gratification, leaves the patient unsatisfied. He therefore greedily resorts to a strengthening of his capacity for hallucination, but there is naturally no corresponding increase in satisfaction.

18 July 1959

(An inability to dream and hatred of common sense) implies
(destructive attacks on all linking and anti-social acting out)

[*see* p. 61, discussion of symbol for 'implies', –❩–].

The anti-social acting out is an attempt to destroy the common sense which the patient cannot get rid of. In analysis it contributes to the danger of murderous attacks on the analyst. The analyst's common-sense interpretations are attacked by being seen and felt as sexual assaults. But does the patient really feel them as sexual assaults, or is this an instance of anti-social (i.e. anti-common-sense) attacks on common sense; a sort of 'You're another' retort to someone who is felt to frustrate?

Social-ism versus Narcissism = Frustration of all instincts.

The aimless wandering is described in terms such as, 'down the road' and, 'I don't know why'. But these terms also give a lively impression of the protesting and bewildered parent who is suspicious but can get no relief for anxiety either through confirmation of anxiety, or final or even temporary dismissal of doubts. Is this his conscience playing up both him and me by being delinquent, by being a delinquent super-ego which knows just how to produce the maximum anxiety?

How does this link up with the common sense? The most obvious would be Freud's early super-ego which he equated or associated with social guilt. If this is so, Freud's denial of guilt before the Oedipal situation, except for social guilt, is a more fruitful theory than Melanie Klein's.[1] But splitting attacks on the super-ego, common sense, would lead to a mass of super-egos – the bizarre objects I spoke of in 'The Differentiation of the Psychotic from the Non-Psychotic Part of the

[1]Klein et al., 1952, *Developments in Psycho-Analysis*, p. 272 et seq.

Personality' (1957 [Volume VI]). It is a murderous super-ego. He rebels against it but it is itself delinquent.

What is the relationship between common sense, super-ego, narcissism?

The super-ego is certainly opposed to his existence: it is opposed, *a fortiori*, to his living. It is opposed to morals, e.g. his dream: his father makes a sexual approach to his wife while he (the patient) looks out of the window helplessly.

* * *

The idea (Prichard, *Knowledge and Perception*) that we come to wonder if we can learn anything at all if we start inquiring how we come to know anything is fallacious in that it depends on the supposition that someone exists who knows more than we know, that what we know is not knowledge because in the eyes of this other person's supposedly superior knowledge what we know is inaccurate. But even when in fact someone else exists who knows more, or even when we know better ourselves – for example when we say we know the sun rises when in fact the earth rotates – that does not invalidate our claim to have a particular piece of knowledge. There is a sense in which it is true knowledge that the sun rises and not accurate that the earth rotates, depending on the context of the phrase.

24 July 1959

The suspicion that the actual events of the session are being turned into a dream came back to me today with X when at one point I suspected that my interpretation was being made into a dream. Thus, he sees a tunnel with a train in it. The train stops. "Won't be able to get cured. Too early and since I just missed it there will not be another for a long time. Minute fragments like faeces . . . two chairs and the three-piece suite; stool-chair. I can't talk properly." Then he started on the 'dream'. It was clear to me that a distinction was being made between talking 'properly' and some kind of talking in visual images.

In an attempt to see how these elements were put together, the first difficulty was that the terrifying super-ego would be put together. When it came to synthesis, after this interpretation, the problem was to see how elements were combined. I suspect that Freud's displacement etc. is relevant; he took up only the negative attitude, dreams as 'concealing' something, not the way in which the *necessary* dream is *constructed*.

[Undated]

The tropisms

The tropisms may be communicated. In certain circumstances they are too powerful for the modes of communication available to the personality. This, presumably, may be because the personality is too weak or ill-developed if the traumatic situation arrives prematurely. But when this situation does arise, all the future development of the personality depends on whether an object, the breast, exists into which the tropisms can be projected. If it does not, the result is disaster which ultimately takes the form of loss of contact with reality, apathy, or mania. And in this context I include in mania feelings of depression that must be distinguished from the depression of the neuroses. In extreme cases it is an agitated melancholia, but it need not be extreme; the maniacal quality may be so slight as to be recognizable as an obsessive depression, but its essential quality is aggressiveness and hate.

If such an object exists, a breast capable of tolerating projective identifications that are thrust into it (for it is to projective identification in relation to the breast that I have now returned), then the outcome may be supposed to be more favourable, or at least in suspense.

Associated with the strength of the tropisms, but probably secondary to it, is an intolerance of frustration. Psychopathologically this has not the fundamental importance of the tropisms; clinically it presents a grave problem as it jeopardizes the analytic approach since frustration is essential to it – not extrinsic.

The action appropriate to the tropisms is seeking. I have so far considered this activity as it might be thought to relate to murder, parasitism, and creation – the three tropisms. Thus, considered individually, the tropisms are seen to issue in seeking (1) an object to murder or be murdered by, (2) a parasite or a host, (3) an object to create or by which to be created. But taken as a whole, and not individually, the action appropriate to the tropisms in the patient who comes for treatment is a seeking for an object with which projective

identification is possible. This is due to the fact that in such a patient the tropism of creation is stronger than the tropism of murder.

Suppose that the search ends in the discovery of the object, but the object, the primitive breast, is found to be intolerant of projective identification. For the sake of simplicity in exposition I shall suppose that this intolerance shows itself in two main forms: anxiety (persecution) and hate, or apathy. It is these two classes of response that contribute the environmental component in the development of the psychotic part of the personality. Ultimately both lead to the rejection of the tropism which, it must always be remembered, is a part of the projecting personality. But there are important differences in the rejection: the persecuted object causes the personality partly to reintroject the tropism, now exacerbated, and wholly to introject a peculiar form of primitive super-ego hostile to projective identification even as a method of communication, and so, by extension, to all forms of communication. But, as I have said, the tropism has only been partly reintrojected. For the most part it is felt to exist not in the primitive breast which has refused it admission, not in the immature psyche which dare not take it back, but enclosed within the vehicle of communication itself, be that sound, sight, or touch. Thus enclosed, the tropism and its envelope become persecuted and persecuting.

The tropisms are the matrix from which all mental life springs. For maturation to be possible they need to be won from the void and communicated. Just as a breast, or its equivalent, is necessary for the infant life to be sustained, so it is necessary that a mental counterpart, the primitive breast, should exist for mental life to be sustained. The vehicle of communication – the infant's cry, tactile and visual senses – is engaged in order not only to communicate but also to control the tropism. If all goes well the communication, by projective identification, leads (as Melanie Klein has described) to the deposition in the breast of the tropisms that the infant can neither control, modify, nor develop, but which can be so controlled and developed after they have been modified by the object.

If this breaks down, then the vehicle of communication, the contact with reality, the links of every kind of which I have spoken, suffer a significant fate. This applies particularly to the communicating particles that are felt to lie with their enclosed tropisms, rejected by psyche and object alike.

25 July 1959

I shall assume that the patient's fear of the murderous super-ego prevents his approaching the Positions [paranoid-schizoid and depressive positions]. This in turn means that he is unable to dream, for it is in dream that the Positions are negotiated. He therefore postpones this experience till the analytic session in which he hopes he will have support, or perhaps, feeling he has support, dares to have the dream he cannot have without the consciousness of support.

He has to dream – the important thing here is not the content of the dream, but his having to 'dream', a positive transitive act for which a transitive verb is necessary. Not only the creative person needs to dream to accomplish the act of creation involving experience of the Positions, but also the lesser mortal who needs to do it to 'understand' the interpretation, each good interpretation being, as I have said before, an event that is, or should be, significant as one of the selected facts to which Poincaré draws attention. The patient who consistently 'cannot understand' may not simply be resisting, but resisting in a particular way. Indeed it may be that here lies the essential difference between the resistance as something peculiar to the neurotic and relegation to the unconscious, and psychotic destruction of the means for understanding which is associated with an apparently full consciousness of what is ordinarily the furniture of the unconscious. "I do not understand", or, "do not know why", or "do not know how", etc. may be taken either as a *positive* statement of *inability* to dream, or a defiant assertion of a capacity for *not* dreaming.

If this is so, psychoanalytic use of the dream as a method by which the unconscious is made conscious is an employment in reverse of what is in nature the machinery that is employed in the transformation of the conscious into material suitable for storage in the unconscious. In other words, the dream-work we know is only a small aspect of dreaming proper – dreaming proper being a continuous

process belonging to the *waking* life and in action all through the waking hours, but not usually observable then except with the psychotic patient. The possibility of observing it in the psychotic depends on some peculiarity which makes his unconscious observable. Is this peculiarity the dispersal of the ego, 'common sense', the links with reality, leaving the id exposed? At any rate the hypothesis that in an analytic session I can see the patient dream has proved to be very valuable especially with its counterpart of seeing the contrasting activity of hallucination.

To return to the patient's fear of the Positions and the potential emergence at that stage of a murderous super-ego: the patient tries to cope with this by dreaming with the analyst – or does he just continue what he does all the time? He may then be so afraid that he produces an artefact that is not a dream but a hallucination, and then can make no use of it because he can get no more from a hallucination than he could get milk from an imaginary breast.

Or he may 'dream' (a) introjectively, (b) projectively.

[Undated]

The Dream is an emotional event of which we usually only hear a report or have a memory, although as we shall see it is a matter of some doubt what we mean when we think, or say, we remember a dream. I wish now to extend the term, 'dream', to cover the kind of events that take place in an analysis of a schizophrenic – events that appear to me to merit the description, 'dreams'.

One of the points I wish to discuss is related to the fact that the actual events of the session, as they are apparent to the analyst, are being 'dreamed' by the patient *not* in the sense that he believes that the events observed by him are the same as the events observed by the analyst (except for the fact that he believes them to be a part of a dream, and the analyst believes them to be a part of reality), but in the sense that these same events that are being *perceived* by the analyst are being perceived by the patient and treated to a process of being dreamed by him. That is, these events are having something done to them mentally, and that which is being done to them is what I call being dreamed – subjected to a process which I hope to describe in more detail.

[Undated]

Schematic presentation of dreaming

Murderous super-ego: therefore avoidance of the depressive positions is achieved by not dreaming, or by dreaming with precautions, e.g. of being with the analyst or, like Y, only allowing the dream to develop when he knows someone is there; instead of quietening down when his mother arrives, his dream appears to become *more* vivid and *worse*. It also explains why X seems to cling so tenaciously to my badness in the session.

First Stage

a. No dreams (in the ordinary sense of night-time phenomena).

b. Dreams suppressed and has hallucinations as a substitute. These hallucinations are excretory, projective.

Second Stage

a. No dreams.

b. Dreams suppressed but has hallucinations as a substitute. These are *intended* to be introjectory, but because of fear of the super-ego and, paradoxically, creating the super-ego by synthesis, it is not rewarding as the true dream would be, and in any case the hallucination cannot yield the free associations etc. which are what make a true dream yield its meaning. So: no free associations and no development of personality is possible. The patient cannot get sustenance from a hallucination.

Third Stage

a. Dreams reported. No free associations and not easily distinguishable from hallucinations – "I was standing at the window as usual." Dream seems to be excretory in function.

b. Confusion. Projective identification – splitting almost exclusively with 'dreaming the session'. That is to say, the session is dreamed; my interpretations and all other events of which he is aware, are not seen, listened to, heard in the ordinary way but are subjected to 'inaccessible-ization'. Thus: train stuck in tunnel – two chairs and a three-piece suite – a stool-chair. Mostly excretory to deal with the ego qualities of the interpretations by dispersal.

Fourth Stage

a. Dreams, more frequent but lacking associations and mostly excretory – arm drops off when he gives a traffic signal, thus indicating uselessness of attempting to warn because parts of the body persist in wanting to be destructive. It lies on the grass – in a tantrum? – but there are no associations. Does the analyst know the meaning, or is it obvious?

b. Introjective and projective. The dream-work intended to convert material into a form where it is compact and can be stored – an important function because of memory. His mind being a kind of 'gut', mental storage seems to mean that the dream is a mental digestive process. The nature of the dream and its function vary according to stimuli. The week-end break seems always to lead to sessional dreaming – I think of the excretory kind, but in later stage perhaps more introjective and retentive.

27 July 1959

I think the fear of dreams must contribute to making the patient anxious to avoid the dream-work of the conscious state. Should it simply be introjection that is avoided? No: because according to me the process of introjection is carried out by the patient's 'dreaming' the current events. Introjection –)– Dreaming, would be the formula [*see* p. 61].

Anxiety in the analyst is a sign that the analyst is refusing to 'dream' the patient's material: not (dream) = resist = not (introject). It may be worth considering, when a patient is resisting, whether the resistance bears characteristics relating it to phenomena Freud described as 'dream-work'. But *Freud* meant by dream-work that unconscious material, which would otherwise be perfectly comprehensible, was transformed into a dream, and that the dream-work needed to be undone to make the now incomprehensible dream comprehensible [*New Introductory Lectures*, 1933a, p. 25]. *I* mean that the conscious material has to be subjected to dream-work to render it fit for storing, selection, and suitable for transformation from paranoid-schizoid position to depressive position, and that unconscious pre-verbal material has to be subjected to reciprocal dream-work for the same purpose. *Freud* says Aristotle states that a dream is the way the mind works in sleep: *I* say it is the way it works when awake (*New Introductory Lectures*, pp. 26–27). Freud says the state of sleep represents a turning away from the world, the real external world, and "thus provides a necessary condition for the development of a psychosis". Is this why X talks of losing consciousness? It follows on dream-work which is intended to be destroyed, or has been destroyed, as part of an attack on linking.

28 July 1959

The dream

The dream is the mechanism by which

1. the ego links the sense data of external experience with the associated conscious awareness of the sense impression;
2. the stream of unconnected impressions and events are made suitable for storing in memory;
3. these stored events are reviewed and one is chosen which enables facts already 'known', i.e. stored, to be harmonized so that the relationship between them is established and the place of each element seen in its relationship to the whole;
4. the interplay between paranoid-schizoid and depressive positions is made possible by a selected fact which is known as the 'harmonizing or unifying fact' spatially, and the 'cause' temporally, or when time is an essential element in the relationship between the elements.

The dream, therefore, is the mechanism by which there comes into operation,

(a) the social conscience, associated with splitting of the super-ego and retreat from the depressive position to the paranoid-schizoid position. This seems identical with the social guilt and true super-ego which can only come into being with the Oedipus complex, but which I think is a highly persecutory super-ego which becomes more persecutory since it is split up. Each split itself becomes a complete super-ego and this leads to further splitting, the fragmentation becoming progressively more minute. This contributes to the state where dreams are 'invisible', wet, and being awake is 'dry';

(b) the individual super-ego, a murderous object, which becomes manifest if synthesis of the fragments of the paranoid-schizoid

position is effected by dream-work bringing the depressive position into being.

Social and individual super-ego both contribute by their fearfulness to patients' need to make destructive attacks in dream mechanism. When this happens in the session, the patient will show fear that he is dead or has lost consciousness, because the dream is that which makes available, as part of the personality, both the events of external emotional reality and the events of internal pre-verbal psychic reality. If the dream-work capacity is destroyed, the patient feels dread which is peculiarly terrifying because it is nameless, and because the namelessness itself springs from the destruction of the patient's capacity for dream-work which is the mechanism responsible for naming.

The domain of the dream

Into the domain of the dream flow the sense impressions associated with the coming into being of the reality principle and the pre-verbal impressions associated with the pleasure-pain principle. None of these can be associated with consciousness, memory, recall, unconsciousness, repression, or suppression unless transformed by dream-work. The domain of the dream is the storehouse in which the transformed impressions are stored after they have been transformed. Dream-work is responsible for rendering pre-communicable material 'storable' and communicable; the same for stimuli and impressions derived from the contact of the personality with the external world. Contact with reality is *not* dependent on dream-work; accessibility to the personality of the material derived from this contact *is* dependent on dream-work. The failure of dream-work and the consequent lack of availability of experience of external or internal psychic reality gives rise to the peculiar state of the psychotic who seems to have a contact with reality but is able to make singularly little use of it either for learning by experience or for immediate consumption.

In this respect the dream seems to play a part in the mental life of the individual which is analogous to the digestive processes in the alimentary life of the individual. Why?

The domain of the dream must be seen as containing an amorphous mass of unconnected and undifferentiated elements. These will

be felt by the patient to be dangerous and bad, or potentially good, according to factors in his personality with which I cannot at present be engaged. In so far as this is clinically recognizable, the form in which it manifests itself is a nameless feeling of dread, but there may be others. In so far as dream-work is operative, the course of events in the vicissitudes of these elements can be seen to take different forms: visual, auditory, haptic, olfactory . . . .

* * *

An example of what I mean by 'dreaming' the environment in which the individual finds himself may be found in the group in the elaboration of a myth such as the story that Newton, seeing an apple fall, discovered the Laws of Gravitation. The statement is the outcome of the dream-work, and its object is the embodiment, in a pictorial symbol, of facts which the individuals in a group need to transform so that they can be stored and recalled at will. The pictorial symbol, once formed and stored, can then be recovered and interpreted by the individual to yield the contents that he has felt he needed to store. A peculiarity of psychoanalysis is that the scientific deductive system is a series of hypotheses about hypotheses about hypotheses . . . (e.g. Freud, *Interpretation of Dreams* [1900a], p. 16), a neurological hypothesis about the individual's hypothesis about himself. Also X's alimentary hypothesis about his hypothesis about his persecuting authority. Also my Kleinian hypothesis about X's hypothesis about his hypothesis about his persecuting authority.

This deserves comparison with the physicist's quantum mechanics hypothesis about basic data which in fact are statistical hypotheses [Northrop, 'Introduction' to Heisenberg's, *Physics and Philosophy*].

1 August 1959

Freud says,

> It is easy to see how the remarkable preference shown by the memory in dreams for indifferent, and consequently unnoticed, elements in waking experience is bound to lead people to overlook in general the dependence of dreams upon waking life and all events to make it difficult in any particular instance to prove that dependence. [*Interpretation of Dreams*, 1900a, p. 19]

My belief is that the dependence of waking life on dreams has been overlooked and is even more important. Waking life = ego activity, and in particular the play of logical thought on the synthesis of elements, i.e. particles characteristic of the paranoid-schizoid position. The function of the dream is to render these elements suitable for storage, and so to constitute the contents of what we call memory. Waking life = ego activity = logical operation. This in turn is essential for synthesis and communicability or public-ation.

"The way in which memory behaves in dreams is undoubtedly of the greatest importance for any theory of memory in general" [*Interpretation of Dreams*, 1900a, p. 20]. In my idea above, the dream symbolization and dream-work is what makes memory possible.

2 August 1959

Vomiting and greed as most recalcitrant symptoms: the intense desire to chew and then to feel it going down; the movement of the jaws, the biting is very satisfactory. Some feeling of rebellion likewise – a kind of "Why-should- I-be-denied-the-good-things-of-life?" attitude. The good things are denied because the desire is to chew, and the object is only within visual grasp. But then the destructiveness is transferred to, and is consequently felt to impregnate, looking itself.

Much the same is true of smell as of sight, in that with neither sense must the object be in the physical contact necessary for biting and chewing. Good smells are felt to be turned into bad by the destructiveness with which they are savoured.

This frustration carries over into a relationship with the man's anus because he is predominantly representing the cruelly destroyed breast. Or, rather, the masculine anus represents it, and is itself a cruelly destructive mouth 'producing' bad smells and bad food.

Stammering is also most recalcitrant. Intolerance of frustration leads to intolerance of stimulation.

* * *

Dreams

> We close our most important sensory channels, our eyes, and try to protect the other senses from all stimuli or from any modification of the stimuli acting on them. . . . The sensory stimuli that reach us during sleep may very well become sources of dreams.
>
> Freud, *Interpretation of Dreams*, 1900a, p. 23

Then why is it that dreams we report, or have reported to us, are so often in terms of visual images?

Is it not a 'modification of the stimuli' reaching us? And could this be something to do with the dream-work as an attempt to achieve 'common sense' as part of the synthesizing function of the dream? It may be an aspect of 'linking' one sense to another; the transformation of tactile stimuli into visual excretions as in hallucination. If this is so, it would fit in with Freud's idea that sleep is to be preserved. [*Interpretation of Dreams*, 1900a, p. 573 et seq.]. The hallucinated patient then *would* be doing what I said he was doing when I described him as taking in the interpretation and evacuating it as far as possible away from himself by 'seeing' it, i.e. visually evacuating it as a hallucination. If this is so, the dream proper may be an attempt at visual and flatus-like evacuation.

Calculus formation notes

There is a need for a sign for 'contributes to' = 'adds to' = 'augments'.

Thus: greed, frustration 'augments' envy.

Also a sign for 'initiates' = 'generates'.

Thus: greed, frustration 'generates' hallucination. Or, frustration, intolerance 'generates' hallucination.

Also a symbol or sign for 'of', meaning 'associated with', so as to express frustration 'of' sexual desire in the sense of the frustration being particularized as to the stimulus involved.

3 August 1959

A dream can be concerned with evacuation of an undesired thought, feeling, image, or with its storage. In either instance it must convert either an empirical external fact or an internal psychic reality into a form that renders it suitable for storage or evacuation. In this respect, too, it seems analogous to a digestive process. But is it? Or is it not that the 'name' of the process is similar to the 'name' of the digestive process? From where does this seeming similarity arise?

4 August 1959

One way of dealing with the problem of scientific evidence for dream theories would be to restrict the search for data to experience shared by analyst and patient, or at which analyst and patient are both present. Such occasions might be all those on which the patient said he had had a dream, or all those on which there appear to be events taking place, e.g. the patient sits up and looks around in a dazed way; the analyst, identifying himself with the patient, feels that the experience the patient is having would be more understandable if the patient were asleep and dreaming.

'More understandable.' Why? Because it is more appropriate to the facts as the analyst sees them. But this means that if the analyst were feeling what the patient seems to be feeling, then he, the analyst, would be disposed to say, "I must have been dreaming".

Just then I found I had been asleep; just before I woke I seemed to be saying to F that I was feeling I was going mad because I could not sort out the feeling I was having in the dream about having a dream and who I was. The dream seemed to be that I was trying to solve the problem I am in fact trying to solve, but with the addition of the fear of going mad – a sort of mental disintegration.

Last night, as I was trying to understand a passage in Quine's *Mathematical Logic* [p. 31] in which 'negative' occurred, I had a dream – having fallen into a sleep or doze – in which a negro appeared. The dream, I thought as I wakened, was associated with 'neg' being both negro and negative. But why did I not write it down then? And now I think of negative and native: 'natives' is associated with memories of India, my mother, and natives as being coloured people like Indians who were 'inferior'. Also 'dative' as being a present, and dates which I liked. 'Ablative', to lift off or take away. Negro, as he appeared in the dream, now seems to me to be not a real person but an ideogram. My theory is that this ideogram has enabled me to store all these ideas which I am now producing – maybe because I am a dreamer. Perhaps there is a class of persons, or a class of dreamers, to which it

might be useful to say some people belong. If so, and if it is true that schizophrenics cannot dream, it would need to be stated that they were not members of that class (a point to remember in the elaboration of a theoretical deductive system for the schizophrenic patient).

What do I mean by saying that the negro in the dream was not a real person? Of course he was not. But I suppose that while I was asleep and in that part of mind, if any, in which I am still asleep, he must have been thought of as just a real person, a fact, what I have called an 'undigested' fact. But now I regard him as an ideogram, and this means that some fact has been 'digested' and that the visual image of the negro, which I am now recalling, is a significant element in the process of (the mental counterpart of) digestion. Are 'undigested facts' then used in the process of 'digesting' other facts? Is their 'indigestibility' a quality that renders them useful for this function, as if it were some kind of container for an eroding liquid which must be able itself to resist the erosion by its contents?

On this basis there is always some 'undigested part' of a dream-product ('dream-product' is usually called the dream itself), although my point is that if the person can dream, then he can 'digest' facts and so learn from experience. Obviously what is needed is to consider what 'digesting' facts consists of in detail.

5 August 1959

α

Frustration, according to Freud, enforces the installation of the reality principle ('Formulations on the Two Principles of Mental Functioning' [1911b], pp. 218–226). But the psychotic with his hatred of reality evades the installation of the reality principle. His intolerance of frustration makes for intolerance of reality and contributes to his hatred of reality. This leads to reinforcement of projective identification as a method of evacuation. This in turn leads to dreams that are evacuations, not introjectory operations – hence 'dreams' of the psychotic, which are really evacuations of such *α* as he has been unable to prevent. The dream-elements in the psychotic dream are really the discarded residue of *α*-elements that have survived mutilations of *α*.

Thus, in the psychotic we find no capacity for reverie, no *α*, or a very deficient *α*, and so none of the capacities – or extremely macilent capacities – which depend on *α*, namely attention, passing of judgement, memory, and dream-pictures, or pictorial imagery that is capable of yielding associations.

But this in turn means that he destroys the capacity for thought which is essential to action in reality and which makes bearable the frustration – an essential concomitant of the interval between a wish and its fulfilment. So the psychotic's attempt to evade frustration ends in producing a personality more than ever subject to frustration without the softening or moderating mechanism that would have been available through *α* and thought. In consequence he is more than ever intolerant of a frustration that is more than ever intolerable. And thus a self-perpetuating situation is created in which more and more frustration is produced by more and more effort devoted to its evasion by the destruction of the capacity for dreaming which, had he retained it, might have enabled him to moderate frustration.

* * *

How does a dream evade frustration? By distortion of facts of reality, and by displacement of facts of reality. In short, by dream-work

on the perception of facts – not, in this context, dream-work on the dream-thoughts except in so far as the dream-thoughts are thoughts portraying the facts. Freud attributes to dream-work the function of concealing the facts of internal mental life only – the dream-thoughts only. I attribute to it the function of evading the frustration to which the dream-thoughts, and therefore the interpretation of dream-thoughts, would give rise if allowed to function properly – that is, as mechanisms associated with the legitimate tasks involved in real modification of frustration. Consequently, since such legitimate tasks always carry an element of frustration, excessive intolerance of frustration short-sightedly leads to the attempt at evasion of the frustration intrinsic to the task of modification of the frustration.

α is concerned with, and is identical with, unconscious waking thinking designed, as a part of the reality principle, to aid in the task of real, as opposed to pathological, modification of frustration.

* * *

Freud, approaching the problem as one of interpreting the dream [*Interpretation of Dreams*, 1900a, p. 136], regards the dream-work as 'distorting' the wish-fulfilment. The α approach regards the wish-fulfilment ≡ frustration-avoidance, and the distortion as being of the *facts* – notably a distortion of the fact of frustration. [≡, the sign for 'equivalent to'.]

But it must be noted that I make a distinction between α which is essential to attention, storage of memory, thinking, the positions, consciousness attached to sense organs, notation, passing of judgement, motor discharge (what about sleep-walking?), and the use to which this developing form of thinking ('originally unconscious', as Freud says, and according to me still unconscious) is put – particularly in its use 'to support increased tensions' or, as I would say, in frustration-avoidance or frustration-evasion.

6 August 1959

α

The waking unconscious thinking. Does this have the function I attribute to α, or does α carry out the transformation of sense impressions which makes these storable in such a form that they are available for waking unconscious thinking? When Y winces at each word said, it seems clear that the words are not, outwardly at least, being transformed by α into a form, 'notation', that makes the experience of the analysis available to him.

But the transformation by α is not all by symbol formation. For example, it is clearly of consequence to know from a particular transaction in which the individual possessor of two apples, when given two more, ends up having four apples, that this peculiarity applies always, namely that if two things of any kind whatever are added to two others of the same kind, the result will be a total of four such objects.

That $2 + 2 = 4$ is sometimes said to be self-evident, an axiom. But it is by no means clear that this is or always has been so, any more than it has always been obvious that if I want something in my room which is out of reach I shall have to leave my chair, walk over to it and fetch it. At some point even the process of walking required thought, probably conscious thought. My suggestion is that it still requires thought, but that it is now waking unconscious thought which has been made possible by α. And it is similarly thanks to the operation of α that it seems obvious that $2 + 2 = 4$. If α has not operated, it is probable that it would not be 'obvious' at all.

At first sight it seems that the mathematical capacities of the individual must depend on an α-operation which effects abstraction or generalization, but as usual these convenient simplifications are, by their nature, only approximations, and in some instances the approximation is found not to be sufficiently close. It is probably more true to say that concretization, pictorial or otherwise, may be inseparable from the faculty of abstraction or generalization. Let us then consider this from a new angle.

Let us first suppose that 2 + 2 is established in the individual's mind as = 4. Let us then remember that it is notorious that the mathematicians have never been able to advance their science with sufficient rapidity to be of service to the biological scientist (Braithwaite, *Scientific Explanation*, p. 49) and still less to the psychoanalyst. (It is usually put the other way round – the psychoanalyst is censured for being unscientific because he cannot produce a calculus which is the counterpart of the scientist's deductive systems, e.g. Eysenck.) Let us then transfer the statement, 1 + 1 = 2, to the field of biological science by considering what happens if 1 rabbit (male) is added to 1 rabbit (female), all enclosed in a suitable hutch. In this instance 1 + 1 may easily be found to make quite a considerably larger number than 2 rabbits. Such a fact, thanks to *α*, may not present any great difficulty. But there are situations in which waking unconscious thought is not enough, and these situations demand a change in mathematical outlook which may be as revolutionary and arduous as the elaboration of a positional geometry from a foundation of Euclidean geometry.

* * *

The Interpretation of Dreams [1900a, p. 54]

Most of the criticisms cited are hostile and indicate the need in a waking state to disparage the dream. This is compatible with the *α*-theory that there is a failure of 'digestion mentally'. It would explain partly why the 'facts' and their ideational counterpart had not been digested if the rational conscious attitude was so hostile to the ideational counterpart of the stimulus, wherever in reality it originated. For such hostility would be likely to inhibit dream-work-*α*, and in so far as the inhibition failed – for after all the patient has dreamed – the hostility now extends to the product of the dream-work.

* * *

Logic and dreams

Logic is possibly that element by which it is hoped to establish coherence between elements that otherwise remain separate and persecutory, as in the paranoid-schizoid position.

8 August 1959

In what way does logic show itself? What signs betray its presence or absence? How can it be seen that the signs employed in logic, whether peculiar to logic or not, are being logically employed? In view of Quine's criticisms (*Mathematical Logic*, pp. 31, 32, 33) of Whitehead and Russell (1927), it seems evident that even the best logicians have great difficulty in being logical.

Is it possible that there is no necessary, inescapable deduction from any premise that is not merely a repetition of a definitory formula? For example, if 'two' means two, and 'and' means and, and 'two' means two, and 'equals' means equals, and 'four' means four, then two and two equals four.

In the instances quoted by Quine it seems as if the symbol or sign, –❩–, has been so abstracted that it has lost precision necessary for the purpose for which Quine wishes to use it. What is the relationship between 'implies', '–❩–', used by Whitehead and Russell, and '–❩–' used by Quine? By what process is 'implies' denuded of its ordinary speech meanings so that it becomes precise? How is it determined when the sign has been sufficiently abstracted from its ordinary speech meanings to give it the required precision, yet not so much that it has become too generalized and so open to Quine's kind of criticism when scientifically employed? It looks as if the ordinary meanings of 'implies' have crept back into Whitehead and Russell's use of the sign, –❩–. If this is so, then the fault does not lie in the sign but in the fact that the sign has to be employed by human beings who are governed, obviously, by the limitations of their mental equipment. This is similar to the situation with other tools. The tool can be made, be it bomb or –❩–, but there still remains the problem of the use to which it is to be put and the motives impelling the person who employs it.

Why have ordinary meanings (if ____ is true then ____ is true; ____ is false or ____ is true; ____ implies ____; if ____ then ____) crept back into the symbol, –❩–, employed by Whitehead and Russell? Or,

alternatively, by what process has Quine stripped off all meanings from '–⊃–' other than some counterpart of 'if ____ then ____'? Consciously one might say that he is in process of stripping it off in the discussion in *Mathematical Logic* (pp. 31–33) and that there it is done by showing that the use of '–⊃–', as Whitehead and Russell use it, can give rise to different trains of deduction all in themselves correct, but leading to deductions that are either contradictory or absurd. (Northrop, Introduction to Heisenberg, *Physics and Philosophy*, pp. 26, 27 on complementarity and contradiction and Freud.) Could this be related to juxtapositions in α of contradictions and absurdities? But the contradictions or absurdities of dreams are different. And the concretization that is involved in verbal images or ideograms may be very important for preserving precision. How do you abstract the generalized idea of 'table'? How do you concretize and keep precise 'implies'? Is it achieved by dream-work similar to the process of abstraction in *Euclid* I.1, or I.5, or I.47?

* * *

X

His statements that he feels anxious – "I don't know why" – may, in addition to being denials, support very strongly, in view of their constant reiteration, my idea that there is a breakdown of dream-work-α, which makes it impossible for the feelings to be ideogrammaticized and so verbalized. This breakdown is due to the need to prevent the synthesis, in the depressive position, of a frightening super-ego.

9 August 1959

Heisenberg: Physics and Philosophy

p. 32 "Influence of physics on the general situation."

No: the influence of physics has simply been to modify the potency of the man with power to use the atomic bomb. It has no political aspect, but advances in physics have had political *consequences*. But Heisenberg shows that his meaning is not properly expressed by his first paragraph when he goes on in the second to show "that every tool carries with it the spirit by which it has been created". And here I think of the theory I put forward that man's tool-making capacity is hypertrophying as the defensive armour of stegosaurus hypertrophied and led to its extinction.

p. 32 "What will be the outcome of this impact of a special branch of modern science on different powerful old traditions?"

I prefer, 'What will be the impact of powerful old traditions on this special branch of modern science?' as alternative reading.

p. 36 "Light could either be interpreted as consisting of electromagnetic waves . . . or as consisting of light quanta, energy packets travelling through space with high velocity. . . . Einstein . . . was not able to dispute the complete contradiction between this wave picture and the idea of the light quanta."

Is it possible that the explanation fundamentally has to be in terms of primitive phantasies? – e.g. elementary particles (paranoid-schizoid), or wave theory (depressive) – because these are limitations in the human mind which cannot be transcended?

p. 37 "No planetary system following the laws of Newton's mechanics would ever go back to its original configuration after a collision with another such system."

The collision and return to normal fit in also with the primitive primal scene.

p. 43 "Instead of asking: How can one in the known mathematical scheme express a given experimental situation? the other question was put: Is it true, perhaps, that only such experimental situations can arise in nature as can be expressed in the mathematical formalism?"

Or can only those phenomena be seen which lie within the scope of man's mathematical capacity? Or can maths and fact come together only if dream-work is available to make abstraction and concretization possible?

10 August 1959

Dream-work-α

Under the title dream-work-*α* I propose to bring together a number of mental activities all of which are familiar to practising psychoanalysts, although they may not have previously associated them together in this way and may not indeed feel the need or value of associating them in the way I propose after they have familiarized themselves with what I am about to say.

The title, 'dream-work', has already a meaning of great value. I wish to extend some of the ideas already associated with it and to limit others. It has seemed to me least likely to cause confusion if I group my ideas under a new title which indicates the affiliations of my ideas and yet makes clear that a distinction is being proposed from the theories already grouped under the term, 'dream-work'.

The main sources, other than the stimulations of psychoanalytic practice and historical affiliations of these grouped ideas, are threefold:

1. Freud's *Interpretation of Dreams* [1900a] and especially the elaboration of his theories of dream-work.

2. Freud's paper, 'Two Principles of Mental Functioning' [1911b] and his *New Introductory Lectures on Psycho-Analysis* [1933a]. Essential to this orientation are the views he expresses on narcissism and the future development of that concept in his paper, 'Instincts and Their Vicissitudes' [1915c].

3. Melanie Klein's theories of splitting, projective identification, and the paranoid-schizoid and depressive positions. In one very important respect I have made extensive use of her description of the difference of her views on guilt and super-ego formation [*Developments in Psycho-Analysis*, 1952, p. 273 et seq. and p. 281 et seq.] from those of Freud in what I want to say about the nature of social guilt, acting out, and delinquency in the psychotic patient.

I shall now set out the characteristics of dream-work-*α*, or, for the sake of brevity, *α*.

Dream-work-*α* is continuous night and day. It operates on the receipt of stimuli arising within and without the psyche. It operates on the mental counterpart of events of external reality, or on what Bradley calls the ideational counterpart of external fact. This ideational counterpart on which *α* operates appears to be the consciousness associated with certain sense impressions, that which Freud calls the consciousness attached to the sense organs [1900a, p. 615]. What this is I am not able to suggest. I have no clinical experience that I feel would be valuable to differentiate from other clinical experiences and label as a part of that which constitutes the consciousness attached to the sense organs. There have been occasions when a patient has spoken of a sensation in a way that made me think it might be an example of a mental phenomenon before it had been transformed by *α*. There have been instances, as I shall show, where the patient speaks of, say, a table in a way that makes it clear that he is not meaning or expressing what is ordinarily meant or expressed when the word is used. The difference usually lies in the fact that for different people the same words have, in addition to their common meaning, a different penumbra of associations. But in the instances that I have in mind the difference lies in what seems to be a *lack* of associations. It is as if the word were a counterpart of the pure note in music, devoid of undertones or overtones; as if, meaning nothing but 'table', it came near to meaning nothing at all.

There are other experiences that appear to be those of emotion, fear, anxiety, dread, to which the patient seems unable to attach either a name or an image, or to recognize them as corresponding to any verbal expression he has ever heard or uttered. In so far as he realizes that the experience is one that he wishes to associate with a cause, he can only say that he has such-and-such a feeling but does not know why. These experiences also appear to be untransformed by *α*. The table is not a memory; it is an indigested fact; it has not been 'dreamed'; it has not been transformed by *α*. The same is true of the emotional experience.

Is it possible to get nearer to describing what *α* does? It pays attention to the sense impression. But in order to do this the impression must be made durable. It must be transformed so that it is suitable

for storage and recall. In short, it has to be submitted to α-activity, and that is impossible unless durability is conferred on the impression and is itself a part of the process by which durability is conferred. The impression must be ideogrammaticized. That is to say, if the experience is a pain, the psyche must have a visual image of rubbing an elbow, or a tearful face, or some such. But now there enters a new feature depending on whether the pleasure-pain or the reality principle is dominant. If the reality principle is dominant, then the object of the ideogram will be to make the experience suitable for storage and recall; if the pleasure-pain principle is dominant, the tendency will be to have as the object of the ideogram its value as an excretable object.

Freud has pointed out that under the dominance of the pleasure principle the object of action is excretion of accumulations of affect (changes of mien etc.), in contrast with action under dominance of the reality principle when its object is to effect changes in environment. In accordance with this, the nature of the visual image will be different if the pleasure principle is dominant from what it would be under the dominance of the reality principle. The grimace of pain or the elbow-rubbing, under pleasure-pain, will be the end-product of a mechanism designed to relieve the psyche of an emotional experience in such a way that the emotional experience can be felt to have been not only excreted but evacuated into a container. In practice, such an omnipotent phantasy can most easily be given the appearance of reality if its expression is not limited to the formation of an ideogram within the psyche, but is expressed through the musculature in an actual grimace of pain or an actual rubbing of the elbow. Muscular action of this kind in the consulting room may sometimes be distinguished from the action designed to change the environment by the peculiarity of the emotional reaction engendered in the beholder. If it is an evacuatory muscular expression of an ideogram, the analyst is aware of having feelings aroused in him which have no component appropriate to action to satisfy those feelings – the evacuating patient's aim is to ensure that the unwanted feelings are inescapably contained in their new receptacle. If the act is carried out under dominance of the reality principle, then the ideogram – whether retained within the psyche or externalized by the musculature – has as its aim a subsequent alteration of the environment. This means that the ideogram expressed by the musculature is felt by the analyst to be by way

of a communication and an invitation to do something – not, as is the case in the contrasting state of expression of an evacuatory ideogram, to be an intrusion into him to which he feels he is passively to submit.

In addition to the effect which depends on the dominance of the pleasure-pain or of the reality principle, there is the effect produced by the degree to which the personality is characterized by an excessive tendency to splitting and projective identification. If the tendency is excessive, then the value of dream-work-*α* is at once altered, for clearly its operation will not aid in the storage of experience if the psyche makes use of experiences that might otherwise be stored in a fund we usually know as memory. But the part played by projective identification is of such wide significance that we shall have to refer to it frequently in other contexts, and I therefore do not propose to elaborate points here which will become clear later.

So far I have had to confess that I cannot really do more than indicate the kind of material that is worked on by *α*. Perhaps the fact that, according to the theory I am attempting to adumbrate, the expression of these very views depends on the operation of *α* and that these views cannot be expressed (according to the same theory) until they have been operated on by *α*, means that there is no way of making a more precise approach verbally. Various kinds of tic, including a stammer, reports of supposed dreams in which there is apparently no content but a powerful emotional experience, reports of dreams in which visual images are devoid of associations of emotion – these for the present appear to be as near as we are likely to get to an understanding of the mental material on which *α* works. To some extent it will be possible to supplement this if we can get to know what the reality is of which the material on which *α* works is the counterpart. The experience that offers most hope of this is the situation in analysis in which it is possible for the analyst to see for himself the current facts on which *α* is operating then and there as the facts unfold.

For the present I must turn to consider further the relationship of *α* to the mechanisms of projective identification and splitting. I shall have more to say later about its relationship to the pleasure principle and the consequences for the wish-fulfilment aspect of dreams. The immediate point is the adverse effect on the personality when the dream-work-*α* is associated with the pleasure principle and excessive projective identification. X's dream of 'looking out of the window as usual' while his father interferes with his wife becomes an evacuatory

process, an attempt to get rid of 'those feelings' by projection of them into me. But do not visual images symbolize or represent in some way? And if so, has no dream-work-*α* taken place? Probably it has; it seems likely that certain feelings have been ideogrammaticized, but *not* for purposes of digestion mentally – only as receptacles to contain, to imprison the idea or feeling and then to eject it. In that case the visual image itself is used as the target for projective identification and then is used as a missile container for further projective identification. If so, perhaps the visual element in dreams is significant because it is felt that the feeling can be excreted further and more effectively if it is put into an object *seen*, perhaps in a hallucinatory manner, because such an object does not need, as with other senses, to be at close quarters for contact. Therefore, in a projectively identified dream, the dream itself is felt to be analogous to a hallucinated object, not for hallucinatory gratification of ingestion, but for hallucinatory excretion. Then the next step – the ejection by the eyes of the hallucination containing the undesired emotional experience.

These feelings preclude the possibility of regarding the dream as a real 'object' – as indeed is the intention – and so preclude the possibility of feeling the dream experience to be potentially effective in its proper function. It is suspect as being only the *appearance* of a life-promoting phenomenon, and so the patient's sense of being unable to dream is unaffected. For the true dream *is* felt as life-promoting, whereas the dream employed as a container for projective identification is felt to be an artefact, as deficient in life-promoting qualities as a hallucinated breast is felt to be deficient in food. But its very function as a container for the unwanted would make it suspect in any case.

The fact that the dream is being employed in an excretory function contributes to the patient's feeling that he is unable to dream or, rather, his thought is far less exact than the phrase, 'unable to dream', would suggest, and does nothing to decrease his feeling that he is lacking in an essential mental capacity.

So far this discussion suggests that a dream exists and that it is characterized by visual images; further, that the dream-work and its production can be employed for two dissimilar purposes. One is concerned with the transformation of stimuli received from the world of external reality and internal psychic reality so that they can be stored (memory) in a form making them accessible to recall (attention) and synthesis with each other.

The other purpose, with which I am here predominantly concerned, is the use of the visual images of the dream for purposes of control and ejection of unwanted (pleasure-pain-determined want) emotional experience. The visual image of the dream is then felt as a hallucinated – that is to say artificially produced – container intended to hold in, imprison, inoculate the emotional experience the personality feels too feeble to contain without danger of rupture, and so to serve as a vehicle for the evacuatory process. The dream itself is then felt to be an act of evacuation in much the same way as the visual hallucination is felt to be a positive act of expulsion through the eyes [*see* 'On Hallucination', *Second Thoughts*, Volume VI, p. 114].

If one kind of patient feels he cannot dream, what does the other kind of patient feel – the kind that feels he *can* dream? I propose to limit the term, 'dream', to the phenomenon as it appears in the light of the common-sense view that we all have dreams, know they occur when we are asleep, and know what they are when we have them. This dream is popularly believed to be due to indigestion: I suggest that the belief expressed in the aphorism, '*in vino veritas*', should be extended to expressions of popular common sense, at least in this instance. In short, I suggest that what is ordinarily reported as a dream should be regarded by us as a sign of indigestion, but not simply physical indigestion. Rather, it should be taken as a symptom of mental indigestion. Or, to phrase it more exactly, as a sign – when a patient reports a dream to us and we are satisfied that he means by this what we all ordinarily understand by a dream – that there has been a failure of dream-work-*α*. The failure may of course be due to precisely such causes as the use of visual imagery in the service of projective identification which I have just been describing, but there are other more common causes of failure of dream-work-*α*, and there are also degrees of frequency with which the patient resorts to the use of dream imagery in the service of projective identification. Investigation of the dream as a symptom of a failure of dream-work-*α* means that we have to reconsider the series of hypotheses that I have grouped together under the heading of dream-work-*α*.

The first cause of breakdown in capacity to dream is associated with the synthesizing function of *α* in relation to the super-ego.

11 August 1959

One of the dangers of the failure to dream α in the session is that the patient then splits the murderous super-ego and evacuates it. He is now surrounded by murderous fragments of super-ego, each of which immediately develops into a super-ego. These, being externalized, are not seen in the real-life objects with which he is surrounded, and a situation is produced similar to that described by Freud as typical of 'social guilt'. Since the patient not only fears but wishes to be re-united with his murderous super-ego fragments, the danger is that he now acts out. And he does this in a way calculated to make the social forces of reality harbour murderous wishes against him. Hence the danger that he will force this by actually committing a murder.

21 August 1959

α

There is a great difficulty in making the step between the scientific deductive system and the low-level hypothesis that is susceptible of clinical verification. The gap between the actual clinical (experimental) data and the theory that is being tested and is to contribute to the formation of an interpretation, seems to me to be very big; it is not only the 'size' of the gap, but the actual dimension in which it exists, which is so difficult to determine. Once the two have been brought together, it becomes simpler.

It is very important that the analyst knows not what *is* happening, but that he *thinks* it is happening. That is the only certitude to which he lays claim. If he does not know that he thinks such-and-such is happening, he has no grounds for making the interpretation. This may help to bridge the gap. The theory that is being subjected to empirical test must be related to its power to enable the analyst to feel certain that he *thinks* that *x* is the case – not to its power to make it certain that *x* is the case. The fact susceptible of empirical test is the certainty, or the degree of certainty, that the analyst can achieve about what he thinks is going on. He could say, "I quite realize that my view may be entirely wrong, but I do know that I am certain at any rate that *this* is my view".

8 September 1959

α

The inability of the psychotic to 'digest' his experience mentally because of his lack of capacity for *α* contributes to the situation with which most observers are familiar, namely the easy accessibility to the *observer* of what should be the psychotic's unconscious. These elements remain detectable because the patient cannot make them unconscious. They are therefore also, as I have shown, not available to *him* because there has been no dream-work-*α* done to make them unconscious and therefore available to him. He is a man both unable to make these elements unconscious and unable to profit by experience, for profiting by experience means being able to make the material consciously perceived into material that can be mentally stored in such a way that it is susceptible of both concretization and abstraction.

A child learning to walk is engaged in attempting to make conscious material unconscious; only when this is done can it walk. The same is true of every piece of learning ever done – its success depends on the central operations by which dream-work-*α* is able to transform conscious material into unconscious material suitable for unconscious waking thinking.

The non-psychotic, and the non-psychotic part of the personality, is afraid of making something conscious – the typical neurotic fear in psychoanalysis – because making it conscious is feared as being the same as 'bringing it out into the open'; this in turn is felt to be the same as evacuating it and making it conscious in such a way that it can never be made unconscious again, and therefore unavailable ever again for unconscious waking thinking. And this in turn is felt to be indistinguishable from being psychotic. This is one of the reasons for the neurotic's fear that successful analysis will make him mad.

The psychotic fears *α* partly because its operation is felt to bring in the super-ego, and partly because making something unconscious is felt to be equivalent to losing it and consciousness for ever, i.e. death.

The neurotic fears interpretation partly because making something conscious is the same as making it unavailable for unconscious waking thought (equivalent to insane state). Unconscious waking thought is occupied with transitions from paranoid-schizoid position to depressive position (Poincaré, *Science and Method*, p. 30).

12 September 1959

In 'Two Principles of Mental Functioning' [1911b] Freud speaks of a capacity for *attention* as associated with the development of the reality principle; he did not follow up this theme. The name seems peculiarly appropriate to a phenomenon I wish to discuss, but I am loath to take over and possibly distort any scientific term already serving a useful function. For this reason I have discarded the term, 'dreamwork', which in some respects covered a number of phenomena bearing an apparent similarity to those I wished to discuss. I considered employing some term such as 'dream-work-*α*', or simply '*α*', but the first only obviated some of the objections implicit in the use of 'dream-work', and the second, though avoiding too strong a penumbra of already-existing associations, erred on the side of being too abstract. The term, 'reverie', had many virtues but carried an implication of divorce from practicality or action, which was alien to my purpose. I hope to avoid a greater number of the possible objections than is possible in the use of any other terms I have considered by using the term, 'attention'. The word does not seem to have been used sufficiently by Freud to make my use of it liable to debase a meaning it already has and so to destroy precision. At the same time it is possible that my use of it may be a legitimate extension of an opening for investigation which Freud made but did not follow up.

13 September 1959

The contact with a psychotic patient is an emotional experience, presenting some precise features that differentiate it from the experience of contact of a more usual kind; the analyst does not meet a personality, but a hastily organized improvisation of a personality, or perhaps of a mood. It is an improvisation of fragments; if the impression is predominantly of friendliness, there will nevertheless be easily discernible fragments of hostility embedded in the conglomerate that has been assembled to do service, for the occasion, as a personality. If the impression is predominantly of depression, the mosaic of fragments will reveal incongruous bits of a smile without context other than a kind of contiguity with surrounding fragments; tears without depth, jocosity without friendliness, bits of hate – all these and many more fragmentary emotions or ideas jostle each other to present a labile façade.

But at once the question arises: is it a façade? If so, what lies behind it? Or, if it means that this improvised personality is all, or nearly all, there is, who or what is responsible for the improvisation? If it is a façade, what does it conceal, and to what end?

The encounter is not unlike the more everyday event of a face-to-face conversation with someone who has a marked squint: at which eye does one look? For the analyst the problem is central, not peripheral. He must decide whether he is speaking to the apparently improvised personality, to the improviser who has had the improvisation forced upon him so as to effect a meeting with the analyst, or to an improviser whose improvisation is one behind which he wishes to remain concealed.

Suppose the patient to be, or to have been, capable of normality: the conglomerate of fragments of personality which serves the patient for a personality can only be regarded as evidence of a disaster. The discussion of such a case is difficult because we are concerned not with the ordinary structures of

the human personality for which terms such as ego, id, super-ego have been made available by Freud, but with the shattered fragments of these which have now been reassembled but not rearticulated.

19 September 1959

Scientific method

Heisenberg shows (*Physics and Philosophy*, p. 89) that a set of concepts has a limitation that is not obvious from the set of concepts itself. The 'set' of relativity and the 'set' of Newtonian mechanics approached each other within the limit where velocities in the system are very small compared with the speed of light.

Similarly it may be true that a scientific deductive system is valid in a certain limited system that is not deductive from the scientific deductive system itself; moreover, that two separate scientific deductive systems approximate to each other in a certain limited system whose limits are not deducible from the concepts of either of the two scientific deductive systems.

In Freud's work the social field in which the individual works is taken as 'given', but now it is essential that the environment must become the object of further theoretical studies. Only in this way can narcissism and the narcissistic psychoses be understood.

* * *

Cogito ergo sum

I am, therefore I think: I think, therefore I am. If α is destroyed, thought becomes impossible and the personality ceases to exist. The schizophrenic's fear of annihilation may be associated with an experiencing of his non-existence as a personality. It raises the question: what is the personality? What is the limiting field for the concept of personality? There can be no personality if there is no thinking, no self consciousness. There may be persons, but not personality unless there is a function of self consciousness. Self consciousness, the function, is the *sine qua non* of personality. To say someone has personality is to mean that he is aware of himself, not sporadically but permanently as a continuous phenomenon.

The stammer is a repudiation of awareness, an evacuation of awareness of what is currently taking place; it is the antithesis of *α*. It is therefore incompatible with a state of self consciousness. And therefore, and to that extent, the stammerer has no personality?

This is not true; any stammerer would I think be said to have a marked personality, often irascible.

26 September 1959

The patient's relationship is, tenuously, with the analyst as analyst; it is predominantly with the couple in the room – any couple, but most obviously the couple formed by the analyst and himself; it is with himself only in a somewhat peculiar manner in that he is either identified with himself or with the couple.

The relationship is not so much with the couple as with the couple as two objects linked together. The predominant element in the relationship between the patient and the couple is that aspect of the relationship which is formed with the link between the two objects. The most obvious link is that provided by his free associations and the analyst's interpretations.

The link changes in character. For my immediate purpose we may suppose that the analyst feels called upon to give a sexual interpretation. He may say, in response to previous material and in accordance with psychoanalytic principles, "You are showing that you feel I am a man doing something sexual to a woman". This statement turns the relationship between analyst and patient into a sexual relationship, and the verbal exchange has become a sexual link.

The patient does not subject this interpretation to α except tenuously and in non-psychotic aspects (parts) of his personality, but of that I do not wish just now to speak. Instead he subjects it to splitting attacks that are destructive in intent; it is taken in only to be subjected to splitting and ejection.

For this purpose mechanisms exist to carry out the double function. The splitting is carried out by some part of the psyche which is symbolically or pictorially represented by teeth, typewriter (working in reverse as it were – the words are taken in aurally, broken up into letters of the alphabet, and thus not only fragmented but transformed from sound into visual objects and ejected through the eyes to become further mutilated, so that they are now minute, unrecognizable shapes at a distance), gramophone (also working in reverse), and so on. The sensory apparatus employed for ejection is related to the distance to

which the fragmented objects are propelled. Visual apparatus is used for distant ejection; tactile sense carries no further than the skin in one direction, and to various organs of the body in the other.

Owing to the conflicting reparative and creative drives, this evacuatory process may not reach the extremes that are represented by invisible visual hallucinations that are the outcome of transformation into pictorial images, extremely minute fragmentation, and ejection by the eyes to a great distance. Some degree of pictorialization and other transformations take place to form the (from the analyst's point of view) bizarre, hallucinatory objects.

This situation which has now developed in the consulting room must be distinguished from that of which I shall treat in the scientific deductive system entitled Hallucination and Dream, dealing with the problem of transition from one position to another when the depressive position is indissolubly linked with the materialization (realization) of a murderous super-ego. For the present I want to consider the fate of the content, the characteristics, of the link between the analyst and patient which has been thus subjected to splitting and evacuation.

"Well then, if you want to know", he said, becoming confidential, "last night I had a most enjoyable evening. People smoking: intelligent, friendly atmosphere, and *then . . .*", becoming indignant, in a noisy voice, "the waitress brought me only half a cup of coffee, and that ab-so-lutely finished it". Dropping his voice, "I couldn't do a thing after that. Not a thing." Almost whispering, "That finished it."

* * *

The schizophrenic's relationship is not with the analyst predominantly but with the analyst + himself. That is to say, it is predominantly a social transference – dualism to narcissism.

The persecutors are products of the *immediate* destruction of the conversation. That is to say, if *a* + *p* are talking sexually, then *p* evacuates as he destroys as he hears the sexual pair. At the same time he reconstructs; his verbal meaning etc. is the reconstruction, and that is audible in the form of his description of the persecutors.

27 September 1959

X has feelings of persecution about various sensory impressions he receives. Are all these sense impressions indications of a process of mental digestion? When he hears banging, is it because he has to get into a state of mind appropriate to being in a mother's inside to spy on her digestive processes – a kind of sexual intercourse in which she (I, in the analysis) is digesting him by banging him to bits, clicking (his frequent complaint) him to bits, just turning him not into a person but a conglomeration of bits of faeces, a stool? In this case his attempt to get into the analyst is identical emotionally with getting 'deeply' into parental sexual intercourse – digestion of one parent by the other. ('Deeply' here means multi-dimensionally extreme – in space, in time, in 'thoroughness', in emotional involvement. A mathematical symbol is required for this concept, or something similarly exact yet abstract.) He has to see the supposed parental intercourse in minute detail and to the bitter end. But as he proceeds, he loses touch with his 'base'.

29 September 1959

Today X was anxious to insist that my voice was stronger and better – that I had got it back again. And as a corollary, that it had been very weak. Obviously the idea was that *he* had put me right – not that he had damaged me. Only if he is allowed to be the analyst can the analysis proceed. But all this is an acting out of phantasy. It differs from normal analysis in which the phantasy has to be interpreted; here it is acted, and the analyst has to agree that the phantasy is a fact.

Drowsiness is coming to me; it is part of the relaxation I have to achieve if my ideas are to be accessible. I must *dream* along, but then I risk going fast asleep. I have had to shut my eyes because they sting. Then I nearly went to sleep. "Watch the wall my darling, while the Gentlemen go by." [Rudyard Kipling, 'A Smuggler's Song'.] A smuggling process I must not know anything about. A wrapping up and packing of the goods I wish to remove from the environment. Does this mean that α is to *hide* things from the conscious? If so, it is nearer to Freud's view of dream-work. The conscious is the servant of the unconscious. It is the conscious whose job it is to lie and deceive and protect the unconscious in its activities.

2 October 1959

X

When I begin to think of an unusually full session, I can remember nothing. This makes me wonder if my wish for his co-operation leads me to exaggerate what he did.

He came into the room handing me his cheque. He lay down from the end of the couch. He speaks. "I wondered whether to write it standing up. I couldn't find a lavatory or a train in which to do it. If I did it downstairs it would keep you standing." Now I am not sure that he did not say, "If I wrote it in the waiting room it would keep you standing", or if it was that if he wrote it downstairs it would keep me waiting. The point is that I suspect that from time to time he speaks with, from his point of view, great precision, and that if I treat it conversationally I am guilty of splashing the good food about, as it were.

Perhaps I should consider schizophrenic precision – a meticulous accuracy – and schizophrenic destructiveness.

4 October 1959

In spite of the advances of science in recent years, the methods employed in scientific work are under critical scrutiny. The moral questioning amongst scientists themselves of the use to which scientific knowledge is being put is scarcely relevant to discussion of the methods themselves, yet it has contributed to that discussion.

In philosophy the question is not new though it is unnecessary to go back earlier than Hume to find the origins of the present controversies. The problem as it appears to the philosopher has been stated by Prichard (*Knowledge and Perception*, p. 69). He says,

> Though we are aware that any knowledge at which we arrive is the result of a process on our part, we do not reflect on the nature of the process – at any rate in any systematic way – and make it the object of a special study. But sooner or later knowledge of our mistakes and the desire to be sure that we are getting the genuine article, i.e. something which is really knowledge, lead us to reflect on the process . . . in the end we find ourselves having to ask whether we are capable of knowing at all and are not merely under the illusion of thinking that we can know.

In the natural sciences the quantum mechanical theories have disturbed the classical concept of an objective world of facts which is studied objectively. And the work of Freud has at the same time excited criticism that it is unscientific because it does not conform to the standards associated with classical physics and chemistry; it constitutes an attack on the pretensions of the human being to possess a capacity for objective observation and judgement by showing how often the manifestations of human beliefs and attitudes are remarkable for their efficacy as a disguise for unconscious impulses rather than for their contribution to knowledge of the subjects they purport to discuss.

But, it may be argued, do not the facts discovered as a result of the application of scientific methods constitute a proof that the methods employed – for example mathematical formulas in the prediction

of astronomical phenomena – have a validity independent of the observer who elaborates and employs them, that the methods belong to ontology, not epistemology, and are 'objective', not 'subjective'? Unfortunately not, for as Heisenberg has shown through the interpretation of quantum mechanical theory made by himself, Niels Bohr, and others of the Copenhagen School, no single fact is unrelated to and uninfluenced by the totality of facts, and that totality must remain unknown. Even the concept of space may have only a very limited application because there need be no reality corresponding to the concept. As Poincaré has pointed out, our methods of mensuration, which have played and still play a considerable part in the concept of space, are clearly related to man's awareness of his own body (*Science and Method*, p. 100), and can in fact be ignored, just as they are in the positional geometry of Riemann. No psychoanalyst would be surprised at the attribution of the origins of mensuration to the experiences of infancy and childhood.

Since the philosophy of modern physics – the most successful and most rigorous of scientific disciplines – can be seen here to be quite compatible with a philosophical view of unco-ordinated and incoherent elements similar to the mental domain of isolated elements from which Poincaré describes the mathematician as attempting to escape by his discovery of the selected 'fact', and since moreover the mental state described by Poincaré is quite compatible or even identical with that described by Melanie Klein in her discussion of the paranoid-schizoid and depressive positions, it is reasonable to suppose that the investigation and explanation of these unco-ordinated elements will be dictated by the impulse described by Poincaré and investigated in detail psychoanalytically by Melanie Klein and her co-workers, and limited by the mental capacity which in the final analysis is the tool by which the investigation is carried out. This in turn means that of the totality of facts, only those will be investigated which are illuminated and rendered comprehensible by existing mathematical calculi. If they lie beyond the scope of such methods, they will not be discovered; if they are discovered, then obviously they will be such facts as conform to, and so appear to confirm, the mathematical calculi that have been employed. There is no reason to suppose that the totality of facts, or even any considerable proportion of them, support the view that there is a realization (Semple and Kneebone, *Algebraic Projective Geometry*, 1952, p. 4) which corresponds to the mathematical calculi

and the scientific deductive systems they represent. For the psychoanalyst there is every reason to regard mathematical phenomena as belonging to the domain of epistemology, and therefore as a matter for psychoanalytic investigation, and in particular that mathematics should be regarded as having, as Heisenberg says of "every word or concept", "only a limited range of applicability" (*Physics and Philosophy*, p. 111). As he says,

> When we represent a group of connections by a closed and coherent set of concepts, axioms, definitions and laws which in turn is represented by a mathematical scheme, we have in fact isolated and idealized this group of connections with the purpose of clarification. But even if complete clarity has been achieved in this way, it is not known how accurately the set of concepts describes reality. [p. 96]

In short, mathematics must be regarded by the psychoanalyst as one of the limiting classes that belong to psychoanalysis in so far as it attempts to be a coherent system of concepts, and in particular as one of the methods by which the paranoid-schizoid and depressive systems are brought into a dynamic relationship with each other, and therefore as an aspect of those mental phenomena that are concerned in the achievement of mental development by facilitating that dynamic relationship. It will therefore be seen that from a psychoanalytic point of view mathematics does not belong to the realm of ontology nor yet even of epistemology, but rather to that class of mental functioning which, since transition from paranoid-schizoid to depressive positions and back is essential to mental development, is essential to sanity itself.

This is not to belittle mathematics but to show how fallacious is the view that pre-eminent importance in any one sphere, however important, confers some universally equal significance in all – a fallacy that has tended to make some observers suppose that failure to produce calculi representing the deductive system of biology, and in particular of psychoanalysis, is necessarily a condemnation of the subject for which no calculi exist. Mathematics may have a very important role as an object of study psychoanalytically, and at the same time and for the same reason be an important element in the mental processes of the individual which makes it possible for him to be a psychoanalyst.

6 October 1959

X

"Have got paint onto my sleeve." He went on and on about this; he couldn't get it off; it might injure my "new couch"; complaints of noises.

Some of the session was explicable in terms of being right inside the mother and witnessing sexual intercourse from there; some in terms of a sexual relationship with me which was achieved by sexualizing a miserable relationship. He spoke of smoke coming from top-storey rooms – two rooms; a fire-engine going to a house where only a week before there had been a fire. These I interpreted as primal scene. But I felt it was more free association on my part to stimuli produced by him. The session had a certain coherence – as interpreted by me. It is extraordinary how little I can have any confidence in the work done; so much seems to be done by myself that any 'result' in the session is open to the objection that it is achieved by the analyst out of his own mind without any element of real contribution by the patient. Yet he criticizes as if any departure from an exactly correct interpretation is an inexcusable imprecision. It is far easier for me to recall an interpretation of mine than the material on which it was based. But nevertheless there were interpretations today which felt right. One touched on the fact that he behaved and felt like a baby – either D or the unborn one – so that the baby would not envy him as the parent. In this way the parent was not allowed to have anything the baby could not have.

The relationship with me is governed by the same watchfulness towards a murderously envious force which appears to be somewhere about. It is often as if material produced for inspection and interpretation is removed in the very act of interpretation. I showed him that a miserable relationship with me was made tolerable by being sexualized.

7 October 1959

X

The pullover which is beautifully knitted by his wife but not suited for the baby's cold. Trains that did not behave as they should (not as frustration-evading dreams). "Had a dream; remembered it as I got off the couch last time. I had painted a picture; stuck on to one corner of it was the payment for it. I don't know how it got there." (Frustration evasion.) He had been talking of his wish to earn a living by painting.

How much should I interpret on classical lines? He showed he did not think it a dream by the way he said, "I don't know how it (the payment) got there". It was therefore quite likely to be more of a hallucination than a dream. And I had been able to show him, with the dream and the two trains, how he expected the trains to act as frustration-evasion items, and not as frustration-modifying 'facts' – real trains which took you somewhere at the cost of tolerating frustration.

This session seems to me so exciting in bearing out, together with previous sessions, the theory of α and the theories about frustration evasion and frustration modification that I can hardly trust myself to bring any kind of reasoned criticism to bear on the matter. Further, there is no doubt of the very great improvement that is taking place.

11 October 1959

Resistance

What is being resisted? The investigation? The interpretation? The emotional experience of investigation? The possibility of the discovery of something? The arousal of emotions? The elements of the paranoid-schizoid position? The junction of paranoid-schizoid with depressive? The onset of the depressive position?

While I write this, considering it is probably all of them, I find myself thinking with hate and fear of Z: a pictorial image of myself standing up at a meeting and attacking him for being a disaster to his profession. And it occurs to me that it is this visual image of which I am frightened. I do not want the experience of the visual image. A fear of this kind, carried far enough, would inhibit or destroy α – the process by which immediate fact is transformed into 'storable' material and not just introjected as undigested fact. Visual image of myself being expelled from the meeting and making a noble, impassioned plea.

The elements are then fragments of the destroyed 'couple', and this fits in with observation of X.

But what of mathematics and music? Geometry is a kind of visual image; music can evoke visual images.

* * *

This question was followed by a long digression of thought and physical activity. Why? Partly because I could not see any further, but partly because I felt I was confronted with unknown elements that do not fit into my scheme or any scheme. Any synthesis always involves more unknowns appearing – that is to say, the appearance of a whole mass of more 'elements'. These presumably require a new deductive system, a new theory, or a part of a new but unknown deductive system. At this point it is clear that the objection to the depressive position is not only the emergence of the object synthesized, but of a whole mass of more unsynthesized objects. Thus one reason for the fear of the synthesized punitive super-ego is that its emergence is

inseparable from the emergence of more 'elements' which are seen, partly in the light of the recreated punitive super-ego, as being fresh evidence of the destructiveness of the personality. It is a revelation not only of past destructiveness but of new destructiveness freshly wrought. A creative act is felt to be the signal for the discovery of a revelation of further and greater tasks of reparation. This contributes to the sense of overwhelming fatigue that some patients experience.

What then leads to resistance in music or maths? To my mind it is the sphinx, the plague (of 'elements'?), the dread of the experience of the paranoid-schizoid/depressive position interplay. Why are the 'elements' so deadly? The animal that goes on four legs, two legs, three legs seems related to the three-kneed thing with equal legs [*see* p. 195].

* * *

The task confronting the analyst is to bring intuition and reason to bear on an emotional experience between two people (of whom he is one) in such a way that not only he but also the analysand gains an understanding of the analysand's response to that emotional situation, and does so through an appreciation of the evidence to which the analyst is drawing attention in the course of his interpretations. It is not enough for the analyst to be convinced that there is evidence for the truth of his interpretations; he must have enough evidence available to afford the analysand the opportunity of being persuaded, by his reason, of the cogency of the interpretation.

Such is the ideal; in fact the analyst's environment, in which I include his state of mind whatever the elements are that contribute to it, and the disturbed mental state of the analysand introduce hazards that make an analysis relate to this ideal with varying degrees of approximation.

The analytic experience is a complex of many experiences, which individually are familiar both to analyst and analysand and therefore tend to give a deceptively simple appearance to a situation that has, by bringing these familiar experiences together, become unique. Everything that happens in a consulting room has happened quite commonly to both participants before, but never in quite the same way. The behaviour that is under observation is in detail the behaviour of ordinary human beings, and even the interpretations given are no different in essence from the kind of interpretations that in ordinary

life we have been used to give and receive throughout our lives, even though we have not so much as heard of psychoanalysis. Nevertheless, the interpretations appear to a layman to be far-fetched and bizarre, a quality they owe to the extension that ordinary interpretative capacity receives through development of the analyst's intuition and the aid he obtains from the body of psychoanalytic theory with which he is familiar.

These theories are always a matter for some degree of controversy even among psychoanalysts, partly because development of the subject means that there are always some theories that are under trial, partly because there are some theories that, though long accepted, seem to require revision, and partly because the application of a theory, perhaps sound in itself, has been defective and so has led to suspicion of the theory.

The theories of psychoanalysis are peculiar in that their use in the consulting room emphasizes, in a manner rare in other sciences, their function as actual tools which the analyst has to use in his practice. In other sciences the theories inform the use to which various tools and appliances are put: in psychoanalysis the theory is the tool itself.

16 October 1959

Various forms of dream manifestation

1. *Organic*

(a) The patient may be concussed – an unlikely contingency but one to be borne in mind in view of the patient's disturbed condition, and therefore the possibility that he has been in an accident.

(b) He may be drunk.

(c) He may have taken some other drug – cocaine, barbiturates, etc.

2. *Psychological*

(a) *α* is in progress. That is to say, he is attempting to transform immediately current events in the room into assimilable form. This pre-supposes that his *α* capacity is rudimentary and is being expressed aloud presumably to get the analyst's help. But it may slide off into

(b) dreaming. This is the emergence of an activity which the patient dare not allow himself out of the analyst's presence through dread of the dream's *manifest* content, and in particular destroyed objects, un-*α*'d objects *and* super-ego.

(c) An artificially contrived dream or a hallucinated dream – the latter must be distinguished from the hallucination. Without this distinction the inability to produce associations cannot be properly understood and there is blurring of the distinction between the process intended to evacuate (hallucination) and a process concerned with a need to introject. The artificially contrived dream *sounds* what it is; it is consciously fabricated, and that, I think, must be taken as the distinction from the hallucinated dream. The hallucinated dream is one produced under duress; the patient *must* dream, and it is this compulsion which leads to an uncontrolled hallucinated dream.

(d) Hallucination: olfactory, auditory, visual. The function is evacuatory, and it is stimulated by immediate events. If the analyst knows the content of the hallucination, then he must see it as an immediate situation not transformed (digested) at all. Thus the patient starts up, pointing and saying, "My wife, it's my wife! She's coming for me! Stop her!" This is a visual image – he is evacuating it through his eyes. It might be argued that this is how he sees me and that I must therefore be transformed mentally into a visual image of his dead wife. In fact it is a view that is plausible but untenable for reasons I shall give later. He does not in any true sense see me or have any other sensory perception of me. I remain an undigested fact because his very partial sensory awareness of my presence has acted as a stimulus to his projective mechanisms and he has ejected an old, undigested fact. I shall not for the moment consider the nature and origin of the visual image of his dead wife, which is here a fact undigested in the past, except to say that it is probably a past dream fragment which he did not originally digest, that it dates from a time when he could dream and that it therefore has great prognostic significance. Indeed it could be taken as a sign suggesting the possibility of psychoanalytic repair and cure because it indicates that there is something to repair. For the moment I want to consider only that, excluding any effect interpretation may have, the original undigested fact, the image of the dead wife, remains undigested; in addition there is a new undigested fact, namely my presence and intervention as the analyst. There is every reason to suppose – again excluding the effect any interpretation may have – that the new undigested fact, in addition to the old one, will at some future date reappear.

17 October 1959

The dream

The term, 'dream', I shall always use for the phenomena described by Freud under that term. The dream is an emotional experience that is developmentally unsuccessful in that it is an attempt to fulfil the functions which are incompatible; it is in the domain of the reality principle and the pleasure principle, and represents an attempt to satisfy both. That is to say, it is an attempt to achieve frustration evasion and frustration modification and fails in both. In so far as it is an attempt at modification of frustration, it requires an interpretation; as an attempt at frustration evasion, it has failed to satisfy because the wish-fulfilment element in it leaves the personality aware that the wish has not been fulfilled in reality. The dream thus occupies a conspicuous role in treatment; it contains, and is itself a manifestation of, painful stresses. But for this same reason its importance is less central amongst the processes involved in the maintenance of smooth development; the crucial mechanisms are those associated with rendering the perceptions of experience fit for storage in the psyche, namely α, and for making these stored transformations of experience available again when the psyche needs them. The problem is, what are these crucial mechanisms? It may be that we can never know, that we can only postulate their existence in order to explain hypotheses that are capable of translation into empirically verifiable data, and that we shall have to work with these postulates without assuming that corresponding realities will at some time be discovered. I regard α as a postulate of this nature.

* * *

α-*destruction*

One consequence is starvation of the psyche in its supply of reality. There is therefore nothing that can be opposed to phantasy. This is

an additional reason for failure to wake up; there is not enough 'up' to wake up to.

Two conditions need differentiation:

1. a feeling that he cannot dream; this is so strong that it inhibits realization that he is dreaming;
2. an actual inability to dream.

The appearance of dreaming that the patient then presents can be due to phenomena that look alike but are actually different, according to whether they are associated with (1) or (2). If (1), then the disjointed elements are *α*-elements that the patient cannot synthesize, e.g. through fear of super-ego, or hatred of reality, or dread of depression. If (2), then the disjointed elements are *β*-elements.

* * *

The aftermath of the destruction of α

The patient is now enclosed in a state of mind that is no longer adequate for his needs. He is mentally and psychically starved of matter necessary for his development. In short, his attempt to evade frustration has, by cutting him off from reality, produced a frustration more intense than any he has tried to avoid. He is 'imprisoned in psychoanalysis'.

The attempt to escape involves the restoration of *α* which has been destroyed by splitting and projective identification; the fragments have to be recovered and reunited. In addition to the difficulties incidental to this, especially great when the fragmentation has been into extremely minute pieces, is the danger I have indicated which is anticipated from the restoration of an extremely destructive super-ego, which restoration is unavoidable if any restoration at all is attempted. Therefore the process of repair is constantly hampered by a coincidental destructive procedure.

The result is a complex and confusing clinical picture in which the analyst must attempt to demonstrate the fragments that the patient attempts to juxtapose. During this process the destructive super-ego emerges, and contemporaneous destructive attempts are made, at the instigation of the super-ego, to undo the attempts at juxtaposition and repair.

Thus the patient will produce a fragment of a visual image. Another fragment will be produced, perhaps many sessions later. If all goes well, more fragments are produced, perhaps with decreasing intervals of time, until at last it becomes possible to indicate the relationship of some of these fragments of visual images to each other. The reaction will show that the dreaded super-ego is discerned by the patient in the shadowy lineaments of the juxtaposed fragments. This is the signal for splitting attacks on the super-ego and further dispersal of the fragments. But the fragmented super-ego engages in destruction on its own account and splits itself in the process of splitting the ego. The mutual destruction conflicts with the still proceeding reparative efforts.

But we must now consider another consequence of the destruction of *α*. Since its destruction makes it impossible to store experience, retaining only undigested 'facts', the patient feels he contains not visual images of things but things themselves. Reciprocally, things themselves are regarded by him in the same way as non-psychotics and the non-psychotic part of his personality regard 'thoughts' and 'ideas'; they are expected by him to behave as if they were visual images in his mind. I have described some of the consequences of this elsewhere; the result I want to consider here is the patient's inability to dream and its exacerbation of the frustration, and its contribution to the frustration that the destruction of a was intended to evade but which has been intensified instead. The starvation of the psyche of all elements needed for growth and development gives extreme urgency to the patient's inability to dream. But this activity is extra-sessional and impregnated with the dangers incidental to a restored super-ego. The fear of this conflicts with the necessity to restore the capacity to dream, for the fear is of nothing less than annihilation. Consequently the patient, as we have already seen, needs to restrict these attempts to sessions. Then, and only then, is he sure of the external aid that the presence of the analyst affords. It is this that leads to the events I have already described in which the patient strives to dream in the session. But, in the instance I am giving, the patient cannot dream. The combination of incapacity to dream with the urgency imposed by psychic starvation gives rise to the phenomenon I have described as the hallucinated dream which affords no associations – associations being equated with sustenance.

25 October 1959

Truth – need for, and need to keep maladjustment in repair

Psychoanalytic procedure pre-supposes that the welfare of the patient demands a constant supply of truth as inevitably as his physical survival demands food. It further presupposes that discovery of the truth about himself is a precondition of an ability to learn the truth, or at least to seek it in his relationship with himself and others. It is supposed at first that he cannot discover the truth about himself without assistance from the analyst and others.

It is likely that this belief has an empirical foundation in that all are familiar with the fact, probably learned very early in life, that a mistaken idea leads to mistaken action, which leads to frustration and other forms of suffering. But a true view can do the same, and on the choice that is made depends the nature of the suffering experienced. The choice is really a choice of method; the essential difference for our purposes in the nature of the choice made is that one is in favour of the method of frustration evasion, and the other in favour of the method of frustration modification. Freud's pleasure principle would seem to tend in the direction of frustration evasion, his reality principle in the direction (in his view) of frustration modification. But in fact, as Freud saw, the impulse to pleasure is not absent under the domination of the reality principle, nor is the reality principle absent under the dominance of the pleasure principle. Much depends on the fact that the choice is influenced by what is, and what is conceived to be, the reality when the choice is made. But the decision is seriously affected by the individual ability or inability to tolerate enduring frustration. If the patient is unable to endure frustration – that is, frustration over a period of time – he will lean towards the methods of frustration evasion.

Whichever choice is made, work has to be done – a point that may escape the attention of the patient, and of those on whom he depends in the most severe cases of all, namely psychotic patients. For the apparatus of denial, endopsychic and social, is formidable indeed if it

is to be as effective as it in fact is. The scientifically minded individual has to be what is ordinarily called well-adjusted, but it is equally true that the individual who is dominated by the goal of frustration evasion has to be what is ordinarily called maladjusted and is under compulsion to keep his maladjustment in constant repair – a point that becomes increasingly clear in the psychoanalysis of the psychotic patient. Nor can his labours cease at the borders of his own personality; as the scientist has to seek the aid of groups, institutions, elaborate apparatus, and social support as well as maintain his mental acumen, so the individual oriented to frustration evasion has to enlist the aid of, or actually initiate, social institutions to help in the task of denial of reality. The actual social institutions need not differ: those used by the scientifically oriented and by frustration-evaders can be the same but used differently. It is obvious that a psychotic will use the institution of marriage, the family and the state differently from the frustration-modifier. What is not sufficiently appreciated is that it is purposive; this becomes clear to the analyst who has to deal with a psychotic patient and his various groups, such as his family. The analyst who is oblivious of this fact and imagines that he can enlist the aid of the family to produce the conditions in which treatment is possible, is ignoring the patient's belief that *he* can enlist the aid of the family and his other groups to produce the conditions in which evasion of frustration is possible. In extreme cases, where murderous destructiveness is directed against the sexual parents and their offspring, the original frustration is of the impulse to murder the parents and commit suicide. This impulse is frustrated by the helplessness of the patient as an infant. With growth this helplessness is removed, but psychological development introduces new barriers to the satisfaction of murderous envy and destructiveness. This struggle between life and death instincts informs the operation of all the complex mechanisms that are demonstrated in the course of an analysis of a psychotic patient. It also contributes powerfully to the patient's need to preserve his psychosis as a complex of methods of frustration evasion, which in turn is felt to be a method by which his murderous impulses are satisfied, and by which he can also satisfy his need to preserve his objects. Both impulses are frustrated, but he strives to evade awareness of either frustration – a goal that cannot be achieved by frustration modification.

30 October 1959

X

He looked clean and cool, rather than sweaty and scruffy as he usually does, then began with the usual evocative associations – evocative *and* provocative, so as to ensure either reassurance of love or reassurance of hate. He was more coherent. *Yet it is hard to recall anything he said*. This is typical even though something is said. I was able to show him that by taking a minutely fragmented view he could avoid feeling the seriousness of the situation, which was revealed if all the minor statements of dissatisfaction were added up. This I think suggests splitting attacks on the depressive position. Thus the depressive stupor becomes a mass of tiny persecutory depressions: the door slams; singing in his head; a pain in his ankle; "I don't know why; I'm sorry; the waitress brought some coffee; only half a cup"; and – despairingly, "*I could not go on*".

This can be regarded as a splitting attack on depression, or an attempt to bring the fragments of persecuting depression together in a creative way, i.e. to form a whole; or a series of pictorial images, ideograms, which will not coalesce; or 'undigested' fragments, i.e. not proper pictorial images but facts sensually perceived yet remaining as bits of sensory awareness that have not been rendered fit for storage and are therefore not memories proper.

This explains my being the person who is dead, who, as he said, has "had it". In other words, if the pieces are brought together and *do* coalesce, it is seen that the fragments are really me, only in pieces. And since I cannot exist like that, I must be dead.

[Undated]

I am reminded of the Millais Culpin case: the patient committed suicide after an interview when Culpin told him that analysis was not suitable for him. Culpin was blamed by the coroner and attacked in *The Times*, which suggested that an end should be put to psychoanalysis.[1]

With this patient it is essential never to forget that one is dealing with a schizophrenic. That is to say that one should never forget that the patient is both murderous and irresponsible, and that 'common sense', i.e. the common sense of the society, dictates a particular diagnosis and a particular attitude of individual members of the society to the patient. Resistance to this dictation carries the penalties which the group always threatens to exact from those who resist its dictates. The 'common sense' of the patient, however invisible and undetectable it may seem to be, tells him this, for he *has* common sense though he makes uncommon use of it.

Although the analyst must never cease to be a member of his group, and must be correspondingly sensitive to its dictates and the risks his ignoring of these dictates carries, neither must he ever permit the 'socialism' of his orientation to obscure the immediate vivid reality that confronts him in the consulting room. The patient knows this too; he is prepared to play his part in exacting a heavy penalty if the analyst does not behave with the perspicacity that is not only demanded by the work, but also by the patient's determination that the analyst should support, by his conduct in devoting his exclusive attention to the patient – no matter at what cost to himself – the patient's narcissism against his 'socialism' (and also be as socially ostracized).

The analyst is thus forced to experience the split which the patient himself suffers between his narcissism and his socialism. That this

[1] [See Culpin (1926a, 1926b). *Ed.*]

split exists is made apparent by the patient's reaction to the analyst's ministrations to his narcissism. We have seen that the patient resents the analyst's awareness of social pressures and obligations, but he equally resents the pressures that originate in the exactions of his narcissism and does so by exploiting the interest the analyst shows in his welfare as a failure on the part of the analyst to show the common sense which everyone, except the analyst, might be supposed to possess.

* * *

The super-ego

The mirror image in time and space, as it appears in *Alice Through the Looking-Glass*, is a version of a psychotic state that bears much the same relation to the psychotic state as do the events in a dream to the anxieties the dream expresses. That is to say, it is a version that makes the intolerable tolerable. The patient who looked at the blood mounting up his sleeve was experiencing murder, or rather being murdered, in reverse. At the point when his blood will be fully restored to his circulatory system he will experience being murdered. And then he will be all right.

Yet this is not quite right. It is far more than a mirror image – perhaps an inverted mirror image, such as might be obtained through a focal point of a lens.

I am not able to co-ordinate what I said about the bizarre objects as being pieces of super-ego or containing pieces of super-ego, with common sense as being the sense of the group and therefore its moral sense. Yet there is some point of intersection (certainly: because the group and its common sense is felt to be indistinguishable from particles of his destroyed common sense).

It may be that the point of entry is the Ps → D, the search for the significant unifying fact which is called 'the cause' when time is a component. It is the synthesis of the murderous super-ego (which takes place at the moment when all other syntheses take place) that makes Ps → D so hazardous.

But in postulating socialism as the other pole of narcissism, I had in mind the idea that the patient's socialism menaces his primacy as an individual, and the group demands of him subordination to aims

lying outside his personality. This is especially true with regard to aggression. Is it also true of morality? Is there a moral instinct which is also bi-polar, one in which the patient is impelled in conflicting directions because his individual moral view conflicts with the moral view he holds as a member of the group?

The conflict in the individual between socialism and narcissism

In his paper, 'Instincts and Their Vicissitudes' [1915c], Freud makes the suggestion that the relation between the ego and sexuality may be regarded in two apparently equally well justified ways. In the one, the individual is regarded as of prime importance; in the other, as a transitory appendage to the germ plasm bequeathed to him by the race. He postulates, expressly disavowing any greater authority for his statement than that appertaining to a postulate, that the conflict is between sexuality and the ego instincts. He suggests that study, particularly of the schizophrenias, might require modification of the theory.

I agree that one side of the conflict is associated with the ego, but it seems to me that difficulties are caused by making a division between ego instincts on the one hand and the sexual instincts on the other. A more fruitful division is one between narcissism on the one hand, and what I shall call socialism on the other. By these two terms I wish to indicate the two poles of all instincts. This bi-polarity of the instincts refers to their operation as elements in the fulfilment of the individual's life as an individual, and as elements in his life as a social or, as Aristotle would describe it, as a 'political' animal. The exclusive mention of sexuality ignores the striking fact that the individual has an even more dangerous problem to solve in the operation of his aggressive impulses, which, thanks to this bi-polarity, may impose on him the need to fight for his group with the essential possibility of his death, while it also imposes on him the need for action in the interests of his survival. There need be no conflict, but experience shows that in fact there is such a conflict – not between sexuality and ego instincts, but rather between his narcissism and his socialism, and this conflict may manifest itself no matter what the instincts are that are dominant at the time.

The ego is involved, for the ego is that which establishes a connection with internal and external realities. It is therefore within the ego that the conflict between narcissism and socialism has to be fought out. This struggle contributes to the forces that lead, in certain circumstances, to the splitting – and in extreme cases the weakening and finally the destruction – of the ego. But the ego is also under attack because it is the part of the personality that leads to the awareness of the conflicting demands of the group and the individual and is therefore felt to be the cause of the pain the individual experiences on account of the ego's contact with both external or group realities, and internal or ego-centric realities – i.e. because of its contact with the demands of narcissism and socialism. There is, therefore, in extreme cases, a weakening or even destruction of the ego through splitting attacks that derive from the primitive instinctual drives which seek satisfaction for both poles of their nature and turn against the psychic organ that appears to frustrate both alike. Hence the appearance, noted by Freud, of hatred of reality – now hatred of the ego which links with reality – characteristic of the severely disturbed patient seen in the psychoses.

It will be remarked that this view demands a revision of our ideas of the narcissistic neuroses and psychoses: they must be considered as cases in which primary narcissism is matched by an equally strong 'socialism' or group membership.

[Undated]

No free associations

When the patient talks about blood, I know what it means and I can produce plenty of associations, but the patient produces none. So I can either let an association of his pass without proper interpretation, and so feel an opportunity is lost, or I can use my own associations and give an interpretation that, in my giving of it, makes me abandon my position as an analyst and become a participant in *his* game – a game played according to rules of which I am not aware. But I do this if I do *not* give an interpretation.

From this point of view it might be put thus:

P: Blood. Now it's your turn to play.

A: (silent)

P: (to himself) What! Doesn't know what blood is? He must be mad.

A: Blood is your common sense which you feel is seeping away.

P: Yes. (And then follow more remarks which are in fact not comprehensible to me, but are to him because they are part of a game which only he understands. This game is a sexual one – sexual, that is, in the eyes of someone.)

[Undated]

The super-ego

The patient is gay, debonair. What has he to be so cheerful about? He is happily married, has a little son to whom he is devoted; his wife, like himself, is wealthy and devoted to him; his home is charming and – what makes it better – he has done much of the carpentry himself; they have both decorated the rooms. Their friends are many and influential, also interesting and creative; a few are artists whose names are known. All is for the best in the best of all possible worlds – the quotation would be known to him. God, likewise, is in His Heaven, all's right with the world. What then is the matter?

But who said there is anything the matter? The patient certainly has not said so – quite the contrary. The summary of his circumstances that I have given is not only obtained from him but is, as I know, the theme on which he is about to embroider as he comes into the room, the theme and its variations to which I have listened for three years in every session he has attended. His analyst and his response to his analyst's treatment both fit in with the rest of his good fortune; it is a pleasure for him to be treated by so brilliant an analyst as myself, and naturally a pleasure for me to have such an agreeable and rewarding patient.

Occasionally there seems to be some discordant note, an interpretation that, after I have given it, seems not to have been quite happy. The patient is, however, able to pass it off with the kind of easy tact with which an accomplished host or hostess – perhaps the latter conveys the more accurate impression – might pass off the solecism of one of the less sophisticated guests. The surface of urbanity, temporarily almost ruffled, is restored, and we return to 'the analysis'.

I said the patient has not mentioned that anything is the matter, but this is only partly true. At times he reports, somewhat whimsically, experiences, say at a party, which are less than agreeable. A woman, ill-tempered and known to be unpopular, has spoken to him impatiently, harshly almost. I am reminded of the lines,

> The good are so harsh to the clever,
> The clever so rude to the good.
>
> Elizabeth Wordsworth, *St. Christopher and Other Poems: Good and Clever*

Sometimes he has spoken as if the other guests too were hostile. None of the episodes he reports appears by itself to be of any consequence, but the effect of these scattered reports could be cumulative. I assume, of course, that as analyst I am able to be sufficiently sensitive for such impacts to influence me. The wide dispersal of such reports itself plays a part in producing the cumulative effect on me. I am given the impression that the actual events are of infrequent occurrence. But suppose they are not: is it possible that in fact this man is really hated?

The facts, as I know them, are that he reports such trivial episodes about once a fortnight. They are minor elements in the analytic material of the sessions in which they appear – minor, that is, if one accepts the balance of significance that the patient by intonation and emphasis imposes on his material.

Let us suppose that the reports correspond to the actual events the patient experiences both as to character and frequency. In that case, I wonder whether he is not perhaps somewhat naïve and oversensitive, perhaps even persecuted. He may simply be conceited, as I know he is, and incapable of judging his importance, or lack of importance. Certainly this view would be quite compatible with his capacity for exploiting the indulgence that is extended to him to produce a conviction of his own worth as the central factor in the agreeable episodes of his life.

My description makes it appear that there are two alternatives: either that the patient is hated, or that he is overindulged, naïve, and persecuted. But in fact there is no reason why these views should be regarded as alternatives.

[Undated]

α

The elements to which the student at the Pons Asinorum says goodbye [Euclid 1.5] have their counterpart in other mathematical situations. Thus there are the elements that are combined in a particular way to form the notation employed in determinants. But even when the mathematician does not employ the term, there are situations in which it is possible to see that what in fact could with justification be called 'elements' are being combined according to certain rules to produce formulas. These elements seem to vary considerably; it may be interesting to collect them together for investigation.

There are numbers; there are letters of the alphabet; there are points, lines, circles, angles; there are signs such as <, +, –; there are letters of the Greek alphabet, capital and lower case. All without exception are written, and though the marks that the writer makes have names – such as 'greater than', 'plus', 'minus', 'alpha', 'beta' – in fact mathematicians do not appear to use these signs for talking in the way that words are used in conversation. It must be supposed, therefore, that the object in synthesizing these elements is different from the object in verbalization, though the synthesizing process seems similar.

Why do not mathematicians speak mathematics? Is it that a string of mathematical formulas cannot be made to say, "It's a nice day"? Is the vocabulary not big enough? No: it must obviously be that its primary purpose is not conversational, although it is clear that one of the functions of mathematics is public-ation.

We shall have to consider three points: (1) the nature of the elements, (2) the nature of the methods employed to bring them together, and (3) the nature of the objects that are created by the syntheses of the elements (Poincaré, *Science and Method*, p. 30; *The Thirteen Books of Euclid's Elements*, I.1, I.5, I.47).

It may appear that I am suggesting that synthesis must be associated simply with a bringing together of the elements according to some known rule to form, say, a polynomial or a determinant. But we

cannot assume such a restriction and exclude the bringing together of these elements in a quite different manner; for example, in such a way that would issue in a dream, or in some structure such as that suggested by Stendhal's description of a painting as, "*de la morale construite*".

Certainly with the psychotic personality there is a failure to dream, which seems to be parallel with an inability to achieve fully the depressive position. It may therefore be said that the capacity to synthesize issues in two main events: (1) the logical construct, a mathematical formula, sentence, etc. and (2) a dream.

The inability to dream: I leave aside for the present the minute fragmentation etc. that may be associated with an inability to dream or, as I think, with dreams that are devoid of sense impressions, i.e. visual impression, auditory, olfactory, maybe tactile and taste impressions that are felt to be a kind of urination. I concentrate on the situation itself in which the patient has dreams devoid of sensory impressions, or all sense impressions and no dreams. If such a patient reports a dream, I suggest he is really reporting a hallucination and that he always feels it to be a 'queer dream'. I suggest that an inability to dream is itself so serious that the patient is compelled to have a dream, a 'queer dream' that is a counterpart, on the level of dream thinking, of the hallucinatory gratification experienced in waking life when true gratification is impossible.

Seen in this light, X's objection to noise may be his objection to a sense impression as well as to the thing his sense impression conveys to him. The deprivation of sense impression must then lead to an inability to dream and a need to hallucinate sense impressions as a substitute for the dream.

But (and it is striking that I am having great difficulty in remembering or seeing the relationship of each bit of this with the bit that has preceded it or that is coming next) this lack of sensory experience must be related to my theory about 'common sense'. And equally, my theory that his dream is a hallucination will explain adequately (?) why he has no associations. A hallucination of a dream can no more yield associations than a hallucinated breast can yield milk.

This failure to dream is felt as such a grave disaster that the patient continues to hallucinate during the day, to hallucinate a dream, or so to manipulate facts that he is able to feel he is having a dream – which is the daylight counterpart of the night-time hallucination of a

dream. But it is also the attempt to suck a dream out of an experience of reality or actuality. And in this respect the dream that yields no associations and the reality that yields no dreams are alike; they are similar to hallucinatory gratification.

Apparently X can get nothing from analysis. In feeling it is a hallucination in which he cannot have either love or hate, I am an object manipulated – like a masturbatory object – to obtain gratification but which yields none. Why is this? Does it mean that envy is primary and precludes the possibility of any gratification, even hallucinatory gratification?

I cannot be satisfied that this is so. I suspect any 'explanation' of which a 'cause' is an essential part; it seems open to the criticism I have made of the theories of causation, namely that there is no actual cause and that the appearance of one is due to the 'realization' of a scientific deductive system, perhaps a premature or hallucinatory 'realization'.

* * *

[*Later addition to this page*]

24 February 1960

It may be worth considering the attempted transfer of the dreaming function to conscious rational levels of mind instead of the levels, now out of action, on which they usually occur.

January 1960

α and objects

In today's session there were clearly brought together two sets of objects:
